SELECTED WATER RESOURCES ABSTRACTS

VOLUME 15, NUMBER 1
JANUARY 1, 1982

W82-00001 -- W82-00500
CODEN: SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Office of Water Research and Technology, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Office of Water Research and Technology, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Office of Water Research and Technology,
U.S. Department of the Interior

VOLUME 14, NUMBER 1
JANUARY 1, 1981

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through August 31, 1983.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Office of Water Research and Technology. The cumlative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE OFFICE OF WATER RESEARCH AND TECHNOLOGY DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

2. WATER CYCLE

2A. General

PREDICTING LAKE LEVELS BY EXPONENTIAL SMOOTHING,
Department of the Environment, Edmonton. Div. of Design and Construction.
S. D. Koppula.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY7, p 867-878, July, 1981. 2 Fig, 5 Tab, 8 Ref.

Descriptors: *Water level fluctuations, *Flood forecasting, *Lakes, Rainfall-runoff relationships, Model studies, Mathematical models, *Lesser Slave Lake, *Alberta, Planning, Prediction, Storm water, Water resources management, Flood plain management, Water level, Forecasting.

Future water levels of Lesser Slave Lake, Alberta, were estimated using the forecasting technique, Exponentially Weighted Moving Average (EWMA). These predictions are crucial for storm water management and land use in a lake district. Since monthly statistics on the levels of Lesser Slave Lake were available for 1913-1977, the first 720 observations were used to develop initial values for mean level in a given period, seasonal factor in a given period, and trend factor in a given period. The next 60 observations (1973-77) were used to test the forecasting model. Comparisons of the predicted vs. the observed values for 1973-77 showed a general agreement; largest deviations were 1.5 ft. The Box-Jenkins technique, harmonic analysis, and a combination of the two methods were compared with the EWMA model. The EWMA was consistently superior in its predictive value. The composite model was the most satisfactory of the other three methods; harmonic analysis, the least. (Cassar-FRC)
W82-00118

CHARACTERIZING SHORT DURATION RAINFALL INTENSITIES FOR RUNOFF CALCULATION,
Science and Education Administration, Beltsville, MD. Hydrology Lab.
E. T. Engman, and D. M. Hershfield.
Transactions of the ASAE, Vol 24, No 2, p 347-352, March-April, 1981. 13 Fig, 9 Ref.

Descriptors: *Runoff forecasting, *Rainfall distribution, Rainfall-runoff relationships, Hydrographs, Infiltration, Nonpoint pollution sources, Error analysis.

The error inherent in calculating peak runoff from hourly rainfall data is demonstrated by applying a model to actual rainfall events. As the actual rainfall distribution approaches the average hourly depth, the error approaches zero. Errors of over 50% occur when intensities are averaged over the hour so that no precipitation excess is calculated. A procedure was developed for simulating five-min rainfall increments from published hourly data. Using the corrected values gives runoff hydrographs much closer to the measured rainfall. At Colorado Springs, Colorado, 3.15 cm was measured, 3.02 cm simulated; and at Tyler, Texas, 2.58 cm measured and 2.36 cm simulated. The method is limited to storms of two hours or less duration. (Cassar-FRC)
W82-00142

MODELING THE FLUX OF ATMOSPHERIC POLYCHLORINATED BIPHENYLS ACROSS THE AIR/WATER INTERFACE,
Wisconsin Univ.-Madison.
For primary bibliographic entry see Field 5B.
W82-00193

MODELING THE RELATIONSHIP BETWEEN DEVELOPMENT AND STORM WATER AND NUTRIENT RUNOFF,
Louisiana State Univ., Baton Rouge. Coastal Ecology Lab.
C. S. Hopkinson, Jr., and J. W. Day, Jr.
Environmental Management, Vol 4, No 4, p 315-324, July, 1980. 5 Fig, 5 Tab, 15 Ref.

Descriptors: *Storm water, *Urban runoff, *Nutrients, Eutrophication, Model studies, Simulation analysis, Runoff, Rainfall-runoff relationships, Agricultural land, Urbanization, Storm Water Management Model, Nonpoint pollution sources, Louisiana, Mississippi, Rivers, Swamps, Land use, Nitrogen compounds, Phosphorus compounds, Infiltration, Wetlands.

The EPA Storm Water Management Model was applied to the des Allemands swamp forest system in the headwaters of the Barataria Basin, Louisiana. The effects of changing land use patterns on storm water runoff were modeled. By 1995 urban land on the uplands will increase by 321%, primarily at the expense of agricultural land. This urbanization will cause storm water runoff rates to increase by 4.2 fold. Nutrient runoff will increase 28% for N and 16% for P. Lake eutrophication will be a problem unless corrective actions are taken. (Cassar-FRC)
W82-00260

THE CONSERVATIVE EFFECT OF RAINFALL VARIATION ON FERTILISER RESPONSE IN A HUMID ENVIRONMENT,
New South Wales Dept. of Agriculture, Wollongbar (Australia).
G. J. Murtagh.
Search, Vol 11, No 1/2, p 35-36, January/February, 1980. 1 Fig, 2 Tab, 8 Ref.

Descriptors: *Rainfall-runoff relationships, *Fertilizers, *Pastures, Humic areas, Runoff, Soil water, New South Wales, *Australia, Effects, Rainfall rate.

Increased rainfall associated with cyclonic activity was relatively unimportant in maintaining soil water supplies and response to fertilizer in pasture in the subtropical coastal areas of New South Wales, Australia. Since 1946 annual rainfall has increased significantly in the two study areas. Most of the excess rain fell when soil was wettest in February-April. After adjusting for runoff, fertilizer responses increased by only small amounts. This is not true in drier inland areas where runoff losses are less. (Cassar-FRC)
W82-00316

EFFECTS OF TILLAGE AND GYPSUM INCORPORATION ON RAIN RUNOFF AND CRUST STRENGTH IN FIELD SOILS IRRIGATED WITH SALINE-SODIC WATER,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Inst. of Soil and Water.
H. Frenkel, and A. Hadas.
Soil Science Society of America Journal, Vol 45, No 1, p 156-158, 1981. 2 Tab, 16 Ref.

Descriptors: *Irrigation effects, *Rainfall-runoff relationships, *Soil strength, Irrigation, Runoff, Rainfall, *Gypsum, Erosion control, Infiltration, Cropland, *Saline water, Infiltration rate, Permeability, *Negev Desert, Israel.

The northwestern part of the Negev Desert of Israel is increasingly irrigated with saline-sodic waters, introducing sodium into the exchange complex of the soil and possibly reducing infiltration rates and water permeability of the soil. The addition of gypsum in the fall to prevent dispersion and crust formation during the rainy season is recommended. The effects of each of two methods for incorporating gypsum on rain runoff and crust strength were investigated in two fields irrigated with saline-sodic water (electrical conductivity: 5.8 mmhos per centimeter; sodium adsorption rate (SAR): 18) and with fresh water (electrical conductivity: 0.95; SAR: 2.6). The first method involves spreading gypsum on the soil surface after tillage operations and disking it into the top 5 centimeters on ridges that are being built. The second method involves plowing a large amount of gypsum into the soil once every few years, after which the area is left in a very rough state. Runoff was reduced to a minimum (3%) when the soil surface was left in a rough state. When ridging patterns were used, up to 40% of the rainfall per storm was lost, regardless of the direction of the ridge with respect to the area gradient or to gypsum application. These results were obtained from adjacent fields having a general slope of 1% and an annual mean rainfall of 371 mm. The results indicate that surface roughness is far more important than amendments in reducing rainfall runoff. (Carroll-FRC)

GROUND-WATER RESOURCES OF THE WHITE RIVER BASIN, MADISON COUNTY, INDIANA,
Geological Survey, Indianapolis, IN. Water Resources Div.
W. W. Lapham.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-109844, Price codes: A06 in paper copy, A01 in microfiche.
Geological Survey Water-Resources Investigations 81-35, June 1981. 112 p, 42 Fig, 9 Tab, 16 Ref.

Descriptors: Groundwater, *Aquifer characteristics, *Groundwater movement, Glacial drift, Groundwater recharge, Water level fluctuations, Estimating, Hydraulic properties, Seepage, Hydrologic budget, *Model studies, Simulations, Groundwater availability, *Groundwater potential, Water yield, Pumping, Observation wells, Surface-groundwater relations, *Indiana, Madison County, *White River basin.

The ground-water resources of the White River basin in and near Madison County, Ind., were investigated by mapping the aquifers, estimating their hydraulic properties, determining the distribution of potentiometric head in the aquifers, and estimating some of the components of the groundwater budget from data collected in the field. This information was used to construct and calibrate a five-layer digital groundwater flow model. The model was used to provide estimates of the ground-water potential in terms of yield, drawdown, and streamflow depletion. Four confined sand and gravel aquifers interbedded in the glacial drift, a bedrock aquifer, and an unconfined outwash aquifer are the three most important aquifer systems in the study area. Model analysis of eight pumping plans provide a general assessment of the water-yielding potential of the three major aquifer systems in the study area. Model results indicate that, at some locations, yields of as much as 2.5 million gallons per day can be developed. Model simulations also indicate that only pumping near the small streams will reduce streamflow by more than a few percent. In developing the ground-water system in the area, use of many small, scattered well fields that produce less than about 3 million gallons per day, may be more favorable hydrologically than a few, heavily pumped well fields, like the well field northwest of Anderson. 2B. Precipitation

RAINWATER GAUGE,
A. C. Abele.

HENRY S. GR... L URBANA CHAMPAIGN

Group 2B—Precipitation

U.S. Patent No. 4,233,841, 7 p, 9 Fig, 4 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 909, November 18, 1980.

Descriptors: *Patents, *Instrumentation, *Rain gages, Weather, Protection, Housing.

A weather instrumentation station includes a louvered instrument housing containing the weather instruments. An exterior double-walled housing radiation shield is placed over the instrument housing to shield the instrument housing from the sun. A double-walled auxiliary shield may be positioned over at least one side of the housing shield to shield sun rays from the instrument housing on the open side. The housing shield and the auxiliary shield inner walls are formed of thermoplastic or aluminized asbestos material, and the outer walls of stainless steel. The housing shield roof is peaked to forestall accumulation of water and snow. There is also provided a rainwater gauge including a receiving flask with a funnel to channel the rainwater. The ratio of the area of the funnel top inlet opening to its lower outlet opening is preferably ten to one. An elongated, hollow, open-ended, stainless steel cylinder of minimal length may be connected to the perimeter of the funnel upper inlet opening to channel rainwater to the funnel lower outlet opening. The cylinder upper edge is a knife edge to ensure collecting a precise are of rainwater. (Sinha-OEIS)
W82-00068

SOME LIMITING FORMS OF THE POISSON DISTRIBUTION OF ANNUAL STATION PRECIPITATION,
Massachusetts Inst. of Tech., Cambridge.
P. S. Eagleson.
Water Resources Research, Vol 17, No 3, p 752-757, June, 1981. 7 Fig, 10 Ref.

Descriptors: *Storms, *Rainfall, Variability, Precipitation, Poisson ratio, Arid climates, Humid climates, Comparison studies.

Annual station precipitation is represented as a seasonally stationary Poisson arrival process in terms of three random variables: season length, number of storms, and storm depth. The contribution of each factor to variance of the annual total precipitation is determined, and the limiting distribution of the total precipitation derived by letting each variable vanish separately. Three cases are studied using data from Boston, Massachusetts; Pasadena, California; and Riyadh, Saudi Arabia. In humid climates the storm depth variability is the predominant contributor to variance in annual rainfall. In arid climates the variability of number of storms per rainy season is the controlling factor; distribution is highly skewed. These findings are useful in studies of extreme climates, where data is often scarce. (Cassar-FRC)
W82-00132

REPORT ON THE SUMMER MONEX FIELD PHASE,
National Science Foundation, Washington, DC.
J. S. Fein, and J. P. Kuettner.
Bulletin of the American Meteorological Society, Vol 61, No 5, p 461-474, May, 1980. 3 Fig, 1 Tab, 7 Ref.

Descriptors: *Monsoons, *Precipitation, *Rainfall, Weather, India, Satellite technology, Air circulation, Seasonal variation, Wet seasons, Winds, Cyclones, Meteorology, Data collections, Heat budget, Heat, Temperature, Asia, Foreign countries, Floods, Global Weather Experiment, MONEX, Indian Ocean.

The 1979 Summer Monsoon Experiment (MONEX) was designed to study the monsoon in the Indian Ocean and adjacent land areas using satellite and land-based measurements. The Indian monsoon of 1979 was substantially subnormal in precipitation over some inland areas, two weeks late in arriving, and early to break up. The southwest monsoon established fully over the Arabian Sea in July. The Bay of Bengal branch developed on schedule in late May, but later weakened, strengthening again on July 7. Break monsoon conditions developed after July 13. A cyclone in early August caused floods, crop damage, and loss of lives. After this event, the monsoon rains declined. Over Saudi Arabia and in the Arabian Sea, where differential heating of sea and land masses initiates the monsoon, differential heating, total heat budgets, and the structure of an intense heat low and its diurnal changes were studied. During this period soil temperatures as high as 70C were measured. Sea surface temperatures were 28C near shore and 30-34C off shore. The role of planetary-scale variation in controlling the monsoon was striking. The low-level Central Indian Ocean branch of the Somali jet was believed responsible for bringing the monsoon into southern India. Surges from the Southern Hemisphere were observed. Personnel from many U.S. and foreign educational and research institutions participated in the project. Combined MONEX and Global Weather Experiment data should provide unprecedented data for a basic study of monsoons. (Cassar-FRC)
W82-00265

RECENT VARIATIONS IN WINTER EXTRATROPICAL CYCLONE ACTIVITY FOR THE AUSTRALIAN REGION,
Adelaide Univ. (Australia). Dept. of Geography.
A. M. Carleton.
Search, Vol 11, No 1/2, p 37-39, January/February, 1980. 3 Fig, 4 Ref.

Descriptors: *Cyclones, *Precipitation, *Weather patterns, *Australia, Satellite technology, Indian Ocean, Tasman Sea.

Satellite infrared imagery for the winters of 1973-1977 in southern Australia was analyzed using the vortex classification system for extratropical cyclonic cloud vortices. The 1975 winter was nearest to the average in precipitation; 1973 and 1974 had above average precipitation and 1975-1976, below average precipitation. These precipitation trends were related to the longitudinal and latitudinal variations in satellite-observed activity. The longitudinal and latitudinal distribution of cyclogenesis was more critical in explaining the anomalies than its frequency. Fluctuations in the intensity of location of the Indian Ocean trough appeared to be the key circulation factor, with the cyclogenetic zone in the Tasman Sea another important factor. (Cassar-FRC)
W82-00315

HISTORICAL NILE FLOODS AND THEIR IMPLICATIONS FOR CLIMATIC CHANGE,
Washington State Univ., Pullman. Dept. of Anthropology.
For primary bibliographic entry see Field 2E.
W82-00326

2C. Snow, Ice, and Frost

EFFECTS OF VOLCANISM ON THE GLACIERS OF MOUNT ST. HELENS,
Geological Survey, Tacoma, WA. Water Resources Div.
M. M. Brugman, and A. Post.
Available from the Branch of Dist., USGS, 604 Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-D, 1981. 11 p, 8 Fig, 2 Tab.

Descriptors: *Volcanoes, *Glaciers, *Snow, *Ice, Snowmelt, Snow cover, Firn, Runoff, Craters, Mountains, *Washington, *Mount St. Helens, Volcanic ash, Pyroclastic flows, Effects.

The cataclysmic May 18, 1980, eruption of Mount St. Helens removed 2.9 square kilometers of glacier snow and ice including a large part of Shoestring, Forsyth, Wishbone, Ape, Nelson, and all of Loowit and Leschi Glaciers. Minor eruptions and bulging of the volcano from March 27 to May 17 shattered glaciers which were on the deforming rock and deposited ash on other glaciers. Thick ash layers persisted after the May 18 eruption through the summer on most of the remaining snow and ice, and protected winter snow from melting on Swift and Dryer Glaciers. Melting and recrystallization of snow and ice surviving on Mount St. Helens could cause lubricate mudflows and generate outburst floods. Study of glaciers that remain on this active volcano may assist in recognizing potential hazards on other volcanoes and lead to new contributions to knowledge of the transient response of glaciers to changes in mass balance or geometry. (USGS)
W82-00007

ON THE ESTIMATION OF ANTARCTIC ICEBERG MELT RATE,
Oregon State Univ., Corvallis. School of Oceanography.
S. Neshyba, and E. G. Josberger.
Journal of Physical Oceanography, Vol 10, No 10, p 1681-1685, October, 1980. 2 Fig, 17 Ref.

Descriptors: *Antarctic Ocean, *Icebergs, *Melting, Ice, Sea ice, Water quantity, Water supply, Water supply development, Iceberg towing.

Minimum sidewall melt rate of Antarctic icebergs, of possible interest to engineers towing icebergs, was determined after evaluating errors of various methods--field observations, iceberg distribution statistics, laboratory experiments, and theoretical studies. This evaluation permits quantitative first-order correction for the effect of bubbles released from the melting ice on the convective heat transfer and the effect of other forms of iceberg deterioration, besides sidewall melting. At temperatures of 2, 3, 4, 8, and 12C best estimates of melt rates were 5, 10, 17, 55, and 100 meters per year, respectively. (Cassar-FRC)
W82-00166

AERIAL BIOMASS DISTRIBUTION IN AN UNDISTURBED AND DISTURBED SUBARCTIC BOG,
Great Lakes Forestry Research Center, Sault Ste. Marie (Ontario).
R. A. Sims, and J. M. Stewart.
Canadian Journal of Botany, Vol 59, No 5, p 782-786, May, 1981. 1 Fig, 1 Tab, 17 Ref.

Descriptors: *Bogs, *Clear-cutting, Peat bogs, *Biomass, Distribution, Vegetation, Ice, Revegetation, Erosion, Frozen ground, Permafrost, *Subarctic zone.

The differences in aerial biomass between an uncleared and cleared portion of a subarctic treed peat plateau at a single site were measured. A portion of a wooded peat plateau in northern Manitoba was stripped of surface vegetation during powerline construction. Seven years after the clearing of the land, the aerial biomass of the plants growing on the disturbed surface was estimated to be 2098 kg/ha. This figure is only 26.4% of the undisturbed portion's biomass. Surface erosion of the peat was visible. Disturbance of the surface does accelerate erosion and may initiate thawing and deterioration of the ice core. In the study area, tree biomass represented 28.7% of the aboveground biomass. Photosynthetic biomass was 17% in the wooded area and 53% in the disturbed area. Major ericaceous species increased after the clearing of the area. The permafrost persisted at the same depth under the disturbed part as under the adjacent forested part. (Small-FRC)

ILLUSTRATION OF THE ROLES OF SNOW IN THE EVOLUTION OF THE WINTER COVER OF A LAKE,
Trent Univ., Peterborough (Ontario). Dept. of Geography.
W. P. Adams, and N. T. Roulet.
Arctic, Vol 33, No 1, p 100-116, March, 1980. 14 Fig, 12 Ref.

Descriptors: *Slush, *Lake ice, *Snow cover, Cycles, Ice cover, Temperature, Fluctuations, Lakes, Snow, Iced lakes, Ice, Melting, *Spatial distribution, Lentic environment, Winter, Elizabeth Lake, Labrador.

A survey of spatial patterns of snow and ice cover on Elizabeth Lake, Labrador, was conducted in February of 1979. Relationships between snow cover, black ice and white ice (produced by slushing) were examined by SPSS and SYMAP computer maps and programs. Snow cover had two general effects on the patterns of ice cover; it produced an insulating effect which slowed the growth of the underlying ice cover, and it also depressed the sheet of ice below the hydrostatic water level, allowing slushing to occur and thus promoting the growth of white ice. Data from Lake Elizabeth showed agreement with these general patterns upon computer analysis. Areas of lower snow cover represented areas where slushing had occurred due to snow depression of the ice surface and incorporation of snow into slush ice formation. Distributions of white ice on the lake's surface were also found to correspond to snow drifting trends controlled by a west-northwest prevailing wind. Black ice thickness generally decreased towards lake margins, while white ice thickness generally increased in these same areas. The cyclic nature of ice growth illustrated on Lake Elizabeth has great bearing on the nature of peak ice which occurs on the lake. (Geiger-FRC)
W82-00267

SHALLOW CORE SNOW CHEMISTRY OF ATHABASCA GLACIER, ALBERTA,
New Hampshire Univ., Durham. Dept. of Earth Sciences.
D. Butler, W. B. Lyons, J. Hassinger, and P. A. Mayewski.
Canadian Journal of Earth Sciences, Vol 17, No 2, p 278-281, 1980. 3 Fig, 2 Tab, 15 Ref.

Descriptors: *Glaciers, *Chemical composition, Chemical analysis, Ice, Glacier mass balance, Glacier balance, Glacial sediments, Nitrates, Phosphates, Snow, Chemistry of precipitation, *Athabasca Glacier.

Samples were taken from the Athabasca Glacier on August 24, 1978, in the accumulation zone close to the 1978 summer equilibrium line altitude and just above the third icefall at an elevation of 2694 meters. The NO3(-) and PO4(3-) values from Athabasca Glacier ice are much lower than those reported for snow samples from central Alberta. The increased reactive SiO2 values in the central Alberta snows suggest that reactive SiO2 can be introduced into the atmosphere and incorporated into snow and ice by man's activities. The mean Si/Fe ratio from the Athabasca ice is low when compared to those of atmospheric aerosols and the central Alberta snow samples. The mean NO3(-)/PO4(3-) ratio is about twice that of the central Alberta snows, suggesting that anthropogenically diluted aerosols may contain higher concentrations of PO4(3-) relative to NO3(-) than unpolluted air. The NO3(-)/PO4(3-) and SiO2/Fe ratios proceed through maxima at 2.5 and 6-6.5 meters depth in the sample pit. The glacier's yearly net mass balance for the sample area was 1.5 and 2.4-2.7 meters water equivalent for the 1976-1977 and 1977-1978 mass balance years. (Baker-FRC)
W82-00320

2D. Evaporation and Transpiration

A PROPOSED TECHNIQUE TO MEASURE EVAPOTRANSPIRATION USING MICROMETEOROLOGICAL METHODS,
Orange Free State Univ., Bloemfontein (South Africa). Dept. of Agrometeorology.
K. L. Bristow, and J. M. De Jager.
Water SA, Vol 7, No 1, p 49-53, January, 1981. 3 Fig, 1 Tab, 8 Ref.

Descriptors: *Measuring instruments, *Mathematical equations, *Evapotranspiration, Anemometers, Radiometry, Evaporation, Evaporation gauges, Irrigation requirements, Transpiration, Water loss, Energy, Plant-water relationships.

Accurate measurements of crop evapotranspiration are vital to irrigation project managers and researchers in the field of plant-water relationships. A method is described for estimating evapotranspiration using two sets of recording wet- and dry-bulb thermometers and an anemometer. In initial field work on wheat crops conducted over a six day period, a net radiometer was employed, which could be replaced by a sunshine duration recorder. Crop evaporation was compared to pan evaporation, and computed surface temperatures gave good agreement with temperatures measured at the momentum exchange surface. Collected data was plugged into the surface energy budget equation, while a reiterative technique was used to calculate a surface temperature to balance this expression. Through conversion of the latent heat flux term in the balanced equation to a volumetric evaporation, the amount of evapotranspiration was determined. The necessary mathematical data may be computed on a programmable calculator, and the durable equipment can be installed and maintained by untrained personnel. (Geiger-FRC)

REDUCED TRANSPIRATION AND INCREASED WATER EFFICIENCY BY DIURON IN CORN (ZEA MAYS),
Guelph Univ. (Ontario). Dept. of Environmental Biology.
S. Ahmed, and R. A. Fletcher.
Weed Science, Vol 28, No 2, p 180-185, March, 1980. 5 Fig, 5 Tab, 16 Ref.

Descriptors: *Transpiration control, *Diuron, *Herbicides, *Corn, Water use efficiency, Drought resistance, Drought, Crop production, Agriculture.

The effectiveness of low concentrations of a representative phenoxy, triazine, and urea herbicide were evaluated in reducing transpiration and increasing water efficiency in corn production. Diuron (3-(3,4-dichlorophenyl)-1,1-dimethylurea) was the most effective herbicide on both monocotyledon and dicotyledon species. A 40% reduction in transpiration occurred. At all stages of corn growth, foliar applications of low concentrations (0.035 to 0.56 kg/ha) effectively reduced transpiration. For 16 days after treatment, the lower leaves of the corn plants did not wilt and become senescent. Diuron increased water efficiency and this effect was more pronounced when water was limiting. Treated plants used 68% less water than controls for each gram of shoot dry weight produced. Diuron may reduce transpiration and maintain yields in drought periods under field conditions. (Small-FRC)

FLOOD DATA FOR THE SACRAMENTO RIVER AND BUTTE BASIN 1875 TO 1978, SACRAMENTO VALLEY, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
J. C. Blodgett.
Available from the OFSS, USGS Box 25425 Fed. Ctr., Denver, CO 80225, Price: $26.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 80-971, June 1981. 193 p, 10 Fig, 17 Tab, 17 Ref.

Descriptors: *Flood data, *Historic floods, *Flood stages, *Flood profiles, Flow duration, Streamflow, Flood peak, Overflow, Flood discharge, Discharge measurement, Gaging stations, Cross sections, *California, *Sacramento River, *Butte Basin.

Streamflow data at various locations were assembled for the Sacramento River between Red Bluff and Meridian, Calif., and for Butte Basin, which serves as an overflow basin during periods of flooding. Data were obtained from various Federal and State agencies and private sources to document the magnitude of flooding from 1875 to 1978. The assembled data include annual maximum flood stages and discharges for the period of record at gaging stations, and flood stages at numerous staff gages, crest-stage gages, and high-water mark sites throughout the study area. Tabulations of floodflow measurements made at or near gaging stations, including the cross-sectional area of the channel and velocities, are presented. Cross sections of the Sacramento River near Chico Landing surveyed in 1978 and earlier surveys to show the size of Butte Basin have been included. A detailed list of references is presented giving the sources of the data included in this report. Many of these sources present detailed descriptions of flooding at various sites. (USGS)

THE INFLUENCE OF STREAM ORDER AND SELECTED STREAM BED PARAMETERS ON FISH DIVERSITY IN RAYSTOWN BRANCH, SUSQUEHANNA RIVER DRAINAGE, PENNSYLVANIA,
Maryland Univ., Frostburg. Appalachian Environmental Lab.
T. Y. Barila, R. D. Williams, and J. R. Stauffer, Jr.
Journal of Applied Ecology, Vol 18, No 1, p 125-131, April, 1981. 1 Fig, 3 Tab, 19 Ref.

Descriptors: *Stream order, *Diversity indices, *Fish populations, Species diversity, Raystown Branch, Susquehanna River, *Pennsylvania, Stream biota, Aquatic animals.

Stream order proved a satisfactory composite index for correlation with fish diversity in a study of Raystown Branch of the Susquehanna River, Pennsylvania. The following parameters were studied in August and October, 1978, at each of 36 stations along the 165 km length: diversity index, stream order, gradient, maximum width, narrowest width, mean width, mean depth, maximum depth, altitude, total species, total individuals, and 6 most commonly occurring species. Diversity was most highly correlated with stream order, increasing with first through fourth order streams. Fifth order streams had a slightly lower mean diversity index, possibly caused by migration into lower order streams for spawning or problems with sampling. Other physical variables showed predictable relationships with diversity and stream order. (Cassar-FRC)

FLOW RESISTANCE IN VEGETATED WATERWAYS,
Waterloo Univ. (Ontario). Dept. of Civil Engineering.
N. Kouwen, R-M. Li, and D. B. Simons.
Transactions of the ASAE, Vol 24, No 3, p 684-690, 698, May/June, 1981. 8 Fig, 2 Tab, 29 Ref.

Descriptors: *Flow resistance, *Vegetation effects, Streamflow, Plant growth, *Channel flow, Model studies.

A new method to determine the flow capacity of a vegetated channel is presented. The method uses the vegetation's length and stiffness as parameters. Graphs of field data of Manning's coefficient versus the product VR (velocity times hydraulic radius) can be accurately reproduced. A table of stiffness values for various types of vegetation for which flow data were available is included. It is shown that the n-VR method of channel design currently in use is based on the correct premise that n is a function of VR regardless of the relative values of V and R. The limitations of the n-VR method are stated. The advantage of the new method is that it is a numerical method which can be easily incorporated in computer programs for other purposes such as backwater or routing models. (Baker-FRC)

HISTORICAL NILE FLOODS AND THEIR IMPLICATIONS FOR CLIMATIC CHANGE,
Washington State Univ., Pullman. Dept. of Anthropology.
F. A. Hassan.
Science, Vol 212, No 4499, p 1142-1145, June 5, 1981. 2 Fig, 1 Tab, 32 Ref.

Descriptors: *Flooding, *Climatology, *Weather patterns, *Nile floods, Africa, Flood stages, History, Rainfall-runoff relationships, Flood stages.

Although records of Nile flood stages are available for the period from the 7th century A.D. to the present, past attempts to understand the implications of variations in Nile floods for climatic change have been unsatisfactory. This study used three different analytic techniques to detect episodic variations in flood stages, following which an attempt was made to determine the cause of the variations and to relate flood episodes to climate in Africa and Europe. Major episodes of low Nile discharge were noted during the years 930 to 1070 and 1180 to 1350. Major episodes of high Nile floods occurred from 1070 to 1180 and from 1350 to 1470. Short-term fluctuations in Nile flood maxima appear to reflect variations in the contributions from the White Nile, which drains a large area of equatorial Africa, and to match variations in water levels of Lake Chad, which are associated with the poleward movement of the intertropical convergence zone. Therefore, it is concluded that the episodic variations in Nile flood discharge are probably the result of climatic changes that influence precipitation in equatorial Africa. Comparison of data on Nile flood stages, including those for scattered periods prior to the 7th century A.D., indicate that there is also a correlation between low Nile discharge and cold climate in Europe. GROUND-WATER DATA FOR MICHIGAN, 1979,
Geological Survey, Lansing, MI. Water Resources Div.
G. C. Huffman.
Geological Survey Open-File Report 80-1212, 1980. 56 p, 4 Fig, 3 Tab, 120 Ref.

Descriptors: *Groundwater resources, *Michigan, *Water levels, *Aquifers, *Water quality, Water wells, Water yield, Water utilization, Well data, Hydrogeology, Hydrographs, Water level fluctuations, Water analysis, Chemical analysis, Data collections.

This report summarizes data on water levels in 138 observation wells in Michigan and provides information on well locations, depths, altitudes, and aquifers that they tap. Tabulated data include extremes of water levels for 1979 and for the period of record. Also tabulated is the pumpage of most major ground-water users in the State and quality data on selected wells sampled during 1979. In most areas, ground-water levels followed precipitation trends. In areas where precipitation was above normal, such as in the northern part of the State, ground-water levels were generally above average. Elsewhere levels were below average. (USGS)

JANUARY 1980 WATER LEVELS, AND DATA RELATED TO WATER-LEVEL CHANGES, WESTERN AND SOUTH-CENTRAL KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
M. E. Pabst.
Geological Survey Open-File Report 80-958, August 1980. 100 p, 2 Tab.

Descriptors: *Groundwater, *Water level, *Observation wells, *Water level fluctuations, *Irrigation, Groundwater recharge, Aquifers, Hydrologic data, *Kansas, Western Kansas, South-central Kansas.

Water-level measurements were made, mostly in January 1980, in about 1,240 observation wells in western and south-central Kansas. The measurements were made in mid-winter when pumping was minimal and water levels had recovered from the effects of pumping during the previous irrigation season. Annual hydrologic data are provided for relating water-level changes from a 'base-reference year' (predevelopment year), a year of abnormally high rainfall and minimum pumpage (1966), and the previous year (1979). The 'base-reference year' is designated at 1950 for the northwestern and westcentral areas, 1940 for the southwestern area, and 1944 for the south-central area. Water level data in the south-central area also are compared with data for 1974. 'Base-reference-year' water levels are based on measurements made during that year and on interpretation of water-table maps. Data also are provided for relating the average annual water-level changes, saturated thicknesses of the deposits, and percentage changes in saturated thicknesses. (USGS)

GROUNDWATER AVAILABILITY IN ACADIA NATIONAL PARK AND VICINITY, HANCOCK AND KNOX COUNTIES, MAINE,
Geological Survey, Boston, MA. Water Resources Div.
B. P. Hansen.
Geological Survey Open-File Report 80-1980. 8 p, 3 Fig, 12 Ref.

Descriptors: *Groundwater availability, *Water yield, *Wells, *Aquifer characteristics, Geohydrology, Water quality, Saline-freshwater interfaces, Bedrock, Geologic fractures, *Maine, Arcadia National Park, Hancock County, Knox County.

This report presents the results of a preliminary investigation of grund-water availability in Acadia National Park and vicinity, Hancock and Knox Counties, Maine. In general, yield of water from individual wells in unconsolidated surficial deposits is low (0-10 gallons per minute). Several small, unconsolidated deposits may yield moderate quantities (50-100 gallons per minute) but these have not been adequately tested. Yields from 160 wells in the crystalline bedrock range from 0.5 to 100 gallons per minute, with a median yield of 10 gallons per minute. Wells in zones of extensive fracturing or faulting generally have higher than average yields. Zones of fracturing may correspond to lineations which have been mapped by interpretation from topographic maps and aerial photographs. In general, ground water is of suitable chemical quality for public supply. Most ground water is low in dissolved solids and is soft. Iron exceeds 0.3 milligram per liter and manganese exceeds 0.5 milligram per liter in water from some wells. Brackish (salty) water is present in only a few wells at the coast or adjacent to saltwater bodies. Elevated concentrations of Radon-222 have been reported from wells in the granite aquifer. (USGS)

AQUIFER PARAMETER IDENTIFICATION WITH OPTIMUM DIMENSION IN PARAMETERIZATION,
California Univ., Los Angeles. School of Engineering and Applied Science.
W. W-G. Yeh, and Y. S. Yoon.
Water Resources Research, Vol 17, No 3, p 664-672, June, 1981. 11 Fig, 4 Tab, 16 Ref.

Descriptors: *Aquifer characteristics, *Transmissivity, *Parametric hydrology, Hydrology, Optimization, Unsteady flow, Groundwater movement.

A method has been developed for parameter identification in a 2-dimensional, unsteady state groundwater flow. The optimum trade-off between the modeling error and the error associated with the parameter uncertainty may be directly determined without relying on prior geologic information on the aquifer. The coefficients to be identified are transmissivities which vary spatially. Finite elements are used to represent the unknown transmissivity function parametrically as nodal values over a suitable discretization of a flow region. A modified Gauss-Newton algorithm is used for parameter optimization. Covariance analysis estimates the reliability of the estimated parameters. Modeling errors, as represented by a least squares criterion, generally decrease with increases in dimension of the unknown parameter, but errors in data are propagated to a greater degree into the estimated parameters, reducing the reliability of the estimations. This method is shown to be more reliable than the pure zonation method. Two cases illustrate the method for determining the optimum dimension in parameterization. (Cassar-FRC)

HYDRAULIC PROPERTIES OF COAL AND RELATED MATERIALS, NORTHERN GREAT PLAINS,
North Dakota Univ., Grand Forks. Engineering Experiment Station.
B. W. Rehm, G. H. Groenewold, and K. A. Morin.
Ground Water, Vol 18, No 6, p 551-561, November-December, 1980. 5 Fig, 3 Tab, 29 Ref.

Descriptors: *Coal, *Hydraulic properties, *Groundwater, *Mining engineering, *Monitoring, Aquifers, Porosity, Flow, Coal mining, Permeability, Geologic fractures, Drawdown, Water level, *Strip mine wastes, Sand aquifers, Hydraulic conductivity, Coal aquifers.

Data from five study areas where coal and sand beds form important aquifers in the northern Great Plains Region have been summarized. Both sand and coal have similar hydraulic conductivities and specific storage values. Aquitards in the region consist of clay and silt, fractured to varying degrees and with a wide range of conductivities. The hydraulic conductivity of strip mine spoils has a six order of magnitude range, with a mean of 8 x 10 to the minus seventh power meters per second. Variability is related to contouring, seasonal variations, and spatial variation of spoil lithology. The hydraulic properties of coal bearing units vary both within and between mines. Disregard for the heterogeneities of a coal aquifer can result in problems in the development of a dewatering plan and in the prediction of the effect of the mine on local water supply wells. GROUND-WATER MODELING: RECENT DEVELOPMENTS,
GeoTrans, Inc., Reston, VA.
C. R. Faust, and J. W. Mercer.
Ground Water, Vol 18, No 6, p 569-577, November-December, 1980. 2 Fig, 2 Tab, 40 Ref.

Descriptors: *Groundwater, *Computer programs, *Model studies, *Hydrogeology, *Calibrations, Mathematical models, Technology, Computer models, Computer applications, Flow, Data interpretation, Mathematical analysis.

Recent developments in groundwater modeling are reviewed. Current research in this field is influenced by two factors, the state of model evolution and computer capabilities. Groundwater flow in saturated porous media is an area for which models are well-developed because confidence in the results is high. The problem of data adequacy is being addressed in research on parameter estimation. In addition, transport modeling and the boundary integral method, a new solution technique, are the focus of current research efforts. The need to develop accessible models and convenient computer techniques is growing as more uses are found for these tools in hydrology and in administrative professions. (Titus-FRC)

GROUND-WATER FLOW AND URANIUM IN COLORADO PLATEAU,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
N. V. Ortiz, J. A. Ferentchak, F. G. Ethridge, H. C. Granger, and D. K. Sunada.
Ground Water, Vol 18, No 6, p 596-606, November-December, 1980. 17 Fig, 2 Tab, 19 Ref.

Descriptors: *Flow, *Porosity, *Uranium, *Geochemistry, *Groundwater, Hydrogeology, Aquifers, Finite difference methods, Piezometers, Flumes, Pumps, Data interpretation, Permeability, Precipitate, *Colorado Plateau, Ore deposits.

The precipitation of humates at the interface between a humic acid solution and an aluminum potassium sulfate solution was studied in porous media models to gain some insight into the deposition of Colorado Plateau type uranium deposits. The effects of variable flow rates, porous-media layering, mudstone lenses, fluid density differences, and geochemical reactions on the flow phenomenon and the resulting precipitate were evaluated. A numerical model was developed to predict the shape and location of the interface where precipitation occurs. The precipitate of the humic material was found to occur both parallel and perpendicular to the general flow path, at the interface between two solutions. Results also indicate that the precipitate deposits are larger when the contact time between the two fluids is large. Any variation in flow rate can significantly influence the location of the precipitate. The association of precipitate bands with modeled sedimentary features and the similarities between these precipitate bands and actual deposits in the Colorado Plateau suggest that these model studies provide data useful both in understanding and predicting the relations between tabular ore deposits and groundwater flow patterns. HYDROGEOLOGIC DATA FROM TEST DRILLING NEAR VERNA BEACH, FLORIDA, 1978,
Geological Survey, Tallahassee, FL. Water Resources Div.
M. Barker, G. Bowman, and H. Sutcliffe, Jr.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $3.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-634, 1981. 26 p, 7 Fig, 3 Tab, 5 Ref.

Descriptors: *Water quality, *Observation wells, *Rotary drilling, *On-site data collections, *Geohydrology, Lithologic logs, Water sampling, Chemical analysis, Pumping, Drawdown, *Florida, *Verna, Well fields.

Four test wells were drilled in the vicinity of the city of Sarasota well field near Verna, Fla., to provide hydrologic and geologic information. An expedient and economical method of air lifting water samples from isolated water-producing zones while drilling was utilized. Lithologic logs of drill cuttings and geophysical logs, including point resistance and spontaneous potential electric logs, gamma-ray logs, and caliper logs, were made. Chemical quality of water was determined for principal producing zones at each well. Dissolved solids from composite water samples ranged from 313 milligrams per liter in test well 0-1 north of the well field to 728 milligrams per liter in test well 0-3 within the well field. Each test well was pumped to determine maximum discharge, water-level drawdown, and recovery time. A leaking pump column on test well 0-1 prevented accurate measurement of drawdown on the well. Test well 0-2, located east of the well field, had a pumping rate of 376 gallons per minute and 13.11 feet of drawdown after 3 hours and 50 minutes; test well 0-3 had a maximum yield of 320 gallons per minute, a drawdown of 31.91 feet after 2 hours and 35 minutes of pumping, had a recovery time of 20 minutes; and test well 0-4, south of the well field, had a pumping rate of 200 gallons per minute with 63.34 feet of drawdown after 2 hours and 35 minutes. PREDICTED EFFECTS ON GROUND WATER OF CONSTRUCTION OF DIVIDE CUT SECTION, TENNESSEE-TOMBIGBEE WATERWAY, NORTHEASTERN MISSISSIPPI USING A DIGITAL MODEL,
Geological Survey, Jackson, MS. Water Resources Div.
M. S. McBride.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $7.00 in paper

copy, $3.50 in microfiche. Geological Survey Open-File Report 81-649, 1981. 50 p, 25 Fig, 1 Tab, 52 Ref.

Descriptors: *Groundwater, *Waterways, Navigation, *Drawdown, *Forecasting, Model studies, Simulation, Geology, Channeling, Artifical lakes, Dams, Groundwater movement, Wells, Water level, Drawdown, Hydrographs, *Mississippi, *Tennessee-Tombigbee Waterway, Tennessee River, Tombigbee River, *Canal construction.

The Tennessee-Tombigbee Waterway, connecting the Tennessee River in northeastern Mississippi with the Gulf of Mexico, is currently (1980) under construction. The Divide Section, the northernmost 39 miles of the Waterway, will consist, from north to south, of (1) a dredged channel, (2) the Divide Cut, and (3) an artifical lake impounded by the Bay Springs Dam. In all three, water will be at Tennessee River level. A three-dimensional digital model covering 3,273 square miles was constructed to simulate ground-water flow in the Gordo and Eutaw Formations and the Coffee Sand in the vicinity of the Divide Section. The model was calibrated to preconstruction water levels, then used to simulate the effects of stresses imposed by the construction of the Divide Section. The model indicates that the system stabilizes after major changes in conditions within a few months. The Divide Cut acts as a drain, lowering water levels as much as 55 feet. Drawdowns of 5 feet occur as much as 8 miles from the Cut. The 80-foot-high Bay Springs Dam raises ground-water levels by 5 feet as far as 6 miles from its impoundment. Drawdown is not likely to affect public water supplies significantly, but probably will adversely affect a relatively small number of private wells. (USGS)

MODELING GRAIN SORGHUM RATOON CROPPING AND ASSOCIATED RUNOFF AND SEDIMENT LOSSES,
Science and Education Administration, Temple, TX. Blackland Conservation Research Center.
D. L. Stinson, G. F. Arkin, T. A. Howell, C. W. Richardson, and J. R. Williams.
Transactions of the ASAE, Vol 24, No 3, p 631-635, 642, May/June, 1981. 6 Fig, 2 Tab, 7 Ref.

Descriptors: *Sorghum, *Mathematical models, *Crop yield, Runoff, Crop production, Sediments, Soil erosion, Water quality, Soil water, Growth, Agriculture, Ratoon cropping.

A practical method was developed to quantitatively describe the effects of ratoon cropping (producing a new crop without replanting) grain sorghum on water quality and quantity parameters and on crop growth and yield. Simulation was used to evaluate the effects of ratoon cropping grain sorghum on volume and sediment load of runoff water. Also, simulation was used to evaluate the effects on availability of soil moisture as it related to crop growth and yield. A growth crop model and a hydrologic model were combined. In only 9 of the 40 years simulated would a ratoon (second) crop have yielded 1500 kg/ha or more. Runoff, evapotranspiration, seepage, sediment yields, total crop yields, and plant crop yields for ratoon cropping were significantly different at the 5% level from those for single cropping for the 9 years with acceptable ratoon crops. The probability of producing a 1500 kg/ha ratoon grain crop yield starting with a fully recharged soil water profile at the plant (initial) crop harvest time was 70%. (Small-FRC)

SOIL HYDRAULIC STABILITY IN A SUBSURFACE DRAINAGE SYSTEM,
Utah State Univ., Logan. Dept. of Agricultural and Irrigation Engineering.
Z. A. Samani, and L. S. Willardson.
Transactions of the ASAE, Vol 24, No 3, p 666-669, May/June, 1981. 3 Fig, 2 Tab, 6 Ref.

Descriptors: *Hydraulic gradient, *Soil stability, *Soil saturation, Erosion, Drainage systems, Permeability coefficient, Plasticity, Mathematical equations, Estimating equations, Soil water.

An indirect way was developed to evaluate the hydraulic stability of saturated soils in the immediate vicinity of a subsurface drain. Six soils from Utah, one from Ohio, and five from Michigan were tested to identify their hydraulic failure gradients. Plasticity index and hydraulic conductivity were correlated with hydraulic failure. Thus, soil stability and density can be used to estimate the internal water flow gradient at which hydraulic failure of the soil structure will occur. An equation was developed which can be used to estimate the hydraulic failure of soils. An increase in soil density or compaction will increase the value of the gradient of hydraulic failure. Data on hydraulic failure can be used with drainage design information to determine whether a drain envelope is needed. It is also possible to calculate the thickness of the envelope or drain diameter. (Small-FRC)
W82-00115

TRANSIENT SOIL MOISTURE MOVEMENT THROUGH LAYERED SOILS USING A FINITE ELEMENT APPROACH,
Pennsylvania State Univ., University Park. Dept. of Agricultural Engineering.
R. Pall, A. R. Jarrett, and C. T. Morrow.
Transactions of the ASAE, Vol 24, No 3, p 678-683, May/June, 1981. 13 Fig, 1 Tab, 21 Ref.

Descriptors: *Mathematical models, *Fluid flow, *Soil water, Porous media, Flow, Mathematical studies, Finite element method, Darcys law, Soil environment, *Soil water movement.

A numerical model to study transient vertical moisture flow through homogeneous and layered soils under isothermal conditions was developed, which uses a finite element approach. The principles of Darcy law flow and mass balance were applied to each element of a flow system to obtain the soil moisture conditions at each time. The model gave results comparable to the numerical method of Hanks and Bowers (1962). One advantage of the new model is that it can be easily programmed. The model is efficient because it does not use the partial differential equation of unsaturated flow which saves computer time. There is physical meaning to the steps in computation because the physical laws of flow through porous media and mass conservation appear explicitly in the model. Unlike other models, the procedure is straight forward, flexible in application, and does not require complex algebraic manipulation. The model can handle both heterogeneous soil and non-uniform initial moisture conditions. (Small-FRC)
W82-00133

AN INFILTRATION MODEL: DEVELOPMENT AND EVALUATION OF ITS PARAMETERS,
Kentucky Univ., Lexington. Dept. of Agricultural Engineering.
B. N. Wilson, D. C. Slack, and C. L. Larson.
Transactions of the ASAE, Vol 24, No 3, p 670-677, 683, May/June, 1981. 7 Fig, 4 Tab, 21 Ref.

Descriptors: *Mathematical models, *Rainfall infiltration, *Ponding, *Soil water, Infiltration, Mathematical studies, Air-water interfaces, Porous media, Flow, Gravity flow.

An infiltration model, called ART, was developed which considers air viscous forces and models a Buckley-Leverett profile at ponding and subsequent infiltration events. It is based on a constant rainfall rate prior to surface ponding and on the assumption that the surface remains at field saturation for the remainder of the event. It also assumes a deep homogeneous soil profile at a uniform initial moisture content. Gravity and resistance flow components are evaluated by associating them with similar flow components in a modified Green-Ampt-Mein-Larson model. The model is efficient and uses less computer time than other approaches, and explicity demonstrates the physical laws of flow through porous media and mass conservation. The procedure is straight forward, flexible in application, and does not require complex algebraic manipulations. It was developed to handle both heterogeneous soil and non-uniform initial moisture conditions. (Small-FRC)

VARIATION IN MICROBIAL ACTIVITY IN HISTOSOLS AND ITS RELATIONSHIP TO SOIL MOISTURE,
Agricultural Research and Education Center, Belle Glade, FL.
R. L. Tate, III, and R. E. Terry.
Applied and Environmental Microbiology, Vol 40, No 2, p 313-317, August, 1980. 3 Fig, 5 Tab, 11 Ref.

Descriptors: *Microbial degradation, *Soil moisture, Organic soil, *Cropland, Sugarcane, Soil water, Dehydrogenase, Enzymes, Bacteria, Oxidation, Aerobic bacteria, Anaerobic conditions.

Dehydrogenase activity and microbial biomass were examined to further elucidate the factors limiting the oxidation of soil organic matter in drained, cultivated histosols. Biomass provided an indication of the overall variation in microbial populations, whereas dehydrogenase reflected the respiratory rate of the microbial community. The variation of these activities, aerobic carbon metabolism, and aerobic bacterial populations with soil moisture were studied to determine the effects of moisture on overall soil microbial activity and to elucidate the relationship between aerobic and anaerobic catabolism of soil organic matter in Pahokee muck. Dehydrogenase activity was 2- to 7-fold greater in soil cropped to St. Augustinegrass compared with uncropped soil. Biomass ranged from equivalence in the two soils to a 3-fold stimulation in the cropped soil. Biomass in soil cropped to sugarcane approximated that from the grass field, whereas dehydrogenase activities of the cane soil were nearly equivalent to those of the fallow soil. Microbial biomass, dehydrogenase activity, aerobic bacterial populations, and salicylate oxidation rates all correlated with soil moisture levels. These data suggest that within the moisture ranges detected in the surface soils, increased moisture stimulated microbial activity, whereas within the soil profile where moisture ranges reached saturation, increased moisture inhibited aerobic activities and stimulated anaerobic processes.

A COMPARATIVE STUDY OF THREE FORMS OF THE RICHARD EQUATION USED FOR PREDICTING ONE-DIMENSIONAL INFILTRATION IN UNSATURATED SOIL,
Universite Scientifique et Medicale de Grenoble (France). Inst. de Mecanique.
R. Haverkamp, and M. Vauclin.
Soil Science Society of America Journal, Vol 45, No 1, p 13-20, 1981. 9 Fig, 22 Ref.

Descriptors: *Mathematical equations, *Unsaturated flow, *Infiltration, Mathematical analysis, Mathematical models, Finite difference methods, *Soil water, Feasibility studies, Comparison studies.

The performance of three finite difference models, each of which is based on a different means of expressing the Richard transient water transfer equation, is compared with respect to precision, time consumption, and economic feasibility. The three models were tested on both a quasi-analytical solution and on experimental results for two different types of soil and for two upper boundary conditions (Dirichlet and Neumann). The best results were obtained with the Kirchhoff model, which was not affected by weighting problems. The model based on the local balance form of the Richard equation was slightly influenced by weighting errors, but was less time consuming than the model based on the Kirchhoff integral transfor-

mation. The model based on the nonconservative decomposed form of the Richard equation was highly influenced by weighting errors and gave the worst results. The range of operation of the decomposed model is also limited with respect to the choice of mesh ratios. The performances of the three models were independent of the chosen upper boundary condition. Nomograms can be evaluated for the three models, relating as a function of the chosen space and time step the performances of the models in terms of precision, amounts of water infiltrated, and computer time. These nomograms can help the user select the correct discretization scheme for the problem under consideration. Since the tests, which were conducted on two types of soil with totally different hydrodynamic properties, led to qualitatively identical results, it is reasonable to expect similar results on other types of soil. EFFECTS OF TOPSOIL AND SUBSOIL THICKNESS ON SOIL WATER CONTENT AND CROP PRODUCTION ON A DISTURBED SOIL,
Science and Education Administration, Mandan, ND. Northern Great Plains Research Center.
J. F. Power, F. M. Sandoval, R. E. Ries, and S. D. Merrill.
Soil Science Society of America Journal, Vol 45, No 1, p 124-129, 1981. 2 Fig, 7 Tab, 9 Ref.

Descriptors: *Soil water, *Crop production, *Soil profiles, Topsoil, Subsoil, Soil horizons, Land reclamation, Spoil banks, Mine wastes, Crop yields.

There is very little quantitative data on the effects of soil thickness upon crop production in semiarid regions. Soil thickness may affect plant rooting depth and the quantity of soil water available for plant growth. This will affect crop growth potentials, especially when the underlying material is a poor medium for plant root activity, as are sodic mine spoils. The research reported in this paper, which was conducted in connection with mined land reclamation research, involved reconstruction of soil by building a wedge ranging from 0 to 210 cm thick with productive subsoil on top of leveled sodic mine spoils derived from shale. This subsoil wedge was then covered with 0, 20, or 60 cm of topsoil. A fourth treatment involving mixing subsoil and topsoil within the wedge in a 3 to 1 ratio. Alfalfa, crested wheat grass, native grasses, and spring wheat were grown on the plots for five years. Yields of all crops increased as total soil thickness increased to the 90 to 150 cm range. All crops except wheat produced at least 90% of the maximum yield with at least 90 cm of mixed topsoil and subsoil spread over the spoils. Water was extracted from the upper 30 to 90 cm of spoils when the soil-spoil interface was within 90 cm of the soil surface. Thickness of the topsoil had no effect on depth of water extraction. Alfalfa extracted water to about 135 cm if sodic spoils were within 90 cm of the surface and to about 175 cm where spoils were covered with at least 150 cm of soil materials. Depth of water extraction under these two situations was about 120 and 150 cm, respectively, for crested wheatgrass, 80 and 120 cm for native grasses, and 75 and 90 cm for spring wheat. There was no evidence of any accumulation of soil water just above the soil-spoil interface under any situation. (Carroll-FRC)

UNSATURATED WATER FLOW THROUGH A SIMULATED WHEEL TRACK,
Science and Education Administration, Morris, MN.
D. C. Reicosky, W. B. Voorhees, and J. K. Radke.
Soil Science Society of America Journal, Vol 45, No 1, p 3-8, 1981. 10 Fig, 1 Tab, 14 Ref.

Descriptors: *Soil physical properties, *Flow characteristics, *Soil compaction, Soil water potential, Compaction, Tensiometers, Conductivity, Cropland, Hydraulic gradient, Soil moisture retention, Soil porosity, Plant growth.

Soil physical properties which affect plant growth can be altered by wheel-track compaction. This study investigated the effect of a simulated wheel track on water movement and soil matric potential distribution under laboratory conditions. The 2 millimeter fraction of the surface layer of a Barnes loam was packed into a soil container large enough to permit a 40-centimeter wide wheel track to be simulated midway between two plant rows spaced 75 centimeters apart. The simulated wheel track was imposed using a compaction tool attached to a penetrometer proving ring that compacted the soil in 25 square centimeter segments at a pressure of 3.25 kilograms per square centimeter. Miniature spring-loaded tensiometers installed at 5 centimeter grid spacings in the wall of the soil container were used to measure hydraulic head. Water content, bulk density, and penetrometer resistance were measured in experimental runs with soil packed wet and packed dry. The change in the pore size distribution that resulted from increased bulk density significantly affected water flow properties of the soil. There were marked reductions in both saturated and unsaturated conductivity with increase in soil bulk density. The water retention curves were also significantly altered by increasing the bulk density. Lower hydraulic heads and larger hydraulic gradients were found under simulated wheel-tracked compaction than under the non-wheel-tracked area. Two-dimensional plots of hydraulic head at selected times showed that isopotential lines curved around the wheel-tracked area. The data suggest that there is less water flow in the wheel track than in surrounding soil. (Carroll-FRC)

EFFECTS OF MOUNT ST. HELENS ERUPTION ON SELECTED LAKES IN WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
N. P. Dion, and S. S. Embrey.
Available from the Branch of Distr., USGS, 604 Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-G, 1981. 25 p, 11 Fig, 10 Tab, 11 Ref.

Descriptors: *Lakes, *Volcanoes, *Limnology, *Water quality, Chemical property, Physical property, Ecosystems, *Washington, *Mount St. Helens, Spirit Lake, St. Helens Lake, Fawn Lake, Venus Lake, Walupt Lake, Warden Lake, Sprague Lake, Amber Lake, *Volcanic ash.

The cataclysmic eruption of Mount St. Helens altered the physical, chemical, and biological characteristics of numerous Washington lakes. As would be expected, those lakes closest to the volcano were the ones affected most by the eruption. Spirit Lake can now be considered a completely different lake because of its higher altitude, larger area, shallower depth, and changed hydrology, biology, and water chemistry. Water-quality changes were observed only in the lakes situated in the blast zone of the volcano. The changes included increases in most chemical constituents and reductions in transparency. Productivity levels in these lakes, as estimated by chlorophyll a concentrations, probably increased. No chemical or biological changes were observed in lakes that received only ashfall. (USGS)

NITROGEN FIXATION AND THE NITROGEN BUDGET OF A EUTROPHIC IMPOUNDMENT,
National Inst. for Water Research, Pretoria (South Africa).
P. J. Ashton.
Water Research, Vol 15, No 7, p 823-833, July, 1981. 12 Fig, 4 Tab, 29 Ref.

Descriptors: *Nitrogen fixation, *Reservoirs, *Eutrophication, Nutrients, Eutrophic lakes, Lakes, Phosphorus, Nitrification, Ammonification, Anabaena circinalis, Rietvlei Dam, *South Africa.

At Rietvlei Dam, South Africa, eutrophic and N-limited, three summer blooms (1975-77) of Anabaena circinalis produced between 1.1 and 24.5 tons of nitrogen by fixation. This represented 1.4%-46.5% of the total annual inflow of combined N. Soluble organic N is a major part of the N pool in the impoundment, and ammonification and nitrification produce large quantities of inorganic N from organic material. High water temperatures, low concentrations of combined N, and low flow promote the fixation process. The N:P ratios in the outflow show sharp peaks (4, 10, and 18) during summer algal blooms, whereas the inflow N:P ratios remain relatively constant throughout the year, about 1-2. (Cassar-FRC)

Descriptors: *Oxidation, *Methane, *Sediments, Sludge, *Anaerobic conditions, Lakes, Lake Mendota, Wastewater, Iron, Sulfates, Sulfides, Lake sediments, Mud, Wisconsin.

Freshwater sediments were taken from Lake Mendota, a hard-water eutrophic dimictic lake with a mud bottom. The water overlying the sediments is anoxic and contains hydrogen sulfide. The sediments actively produce methane during the entire year. Samples were taken in the deepest section of the lake with a water column depth of 23 meters. Anoxic sediments and digested sewage sludge anaerobically oxidized methane to carbon dioxide while producing methane. This strictly anaerobic process showed a temperature optimum between 25 and 37 degrees C, indicating an active microbial participation in this reaction. Methane oxidation in these anaerobic habitats was inhibited by oxygen. The rate of the oxidation followed the rate of methane production. The observed anoxic methane oxidation in Lake Mendota and digested sewage sludge was more sensitive to 2-bromoethanesulfonic acid than the simultaneous methane formation. Sulfate diminished methane formation as well as methane oxidation. However, in the presence of iron and sulfate the ratio of methane oxidized to methane formed increased markedly. Manganese dioxide and higher partial pressures of methane also stimulated the oxidation. The rate of methane oxidation in untreated samples was about two percent of the methane production rate in Lake Mendota sediments and eight percent of that in digested sludge. This percentage could be increased up to 90% in sludge in the presence of 10 mM ferrous sulfate and at a methane partial pressure of 20 atmospheres. (Baker-FRC)

EXPERIMENTAL STUDIES ON THE EFFECT OF ARSENIC ON MICROBIAL DEGRADATION OF ORGANIC MATTER AND ALGAL GROWTH,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
G. J. Brunskill, B. W. Graham, and J. W. M. Rudd.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 3, p 415-423, March, 1980. 7 Fig, 4 Tab, 41 Ref.

Descriptors: *Eutrophication, *Wastewater disposal, *Arsenic, Water pollution effects, Lakes, Nutrients, Phosphorus compounds, Nitrogen compounds, Phytoplankton, Algae, Organic matter, Bacteria, *Microbial degradation, Degradation, Particulate matter, Chemical reactions, Ontario.

The effects of arsenate and arsenite on microbial degradation of organic matter in lake water were studied in experimental tubes in Lake 303 at the Experimental Lakes Area, Northern Ontario. Results on this lake suggested that addition of domestic sewage to Kam Lake, Northwest Territories, containing 30-50 micromoles per liter of arsenic from gold mine tailing pond water, would restrain eutrophication. Summer degradation of organic matter was not inhibited by As, and dissolved P remained high, making more P available for outflow downstream. Arsenic depressed the rates of formation of particulate P and planktonic uptake of dissolved P. Summer blooms are not expected to be as extensive due to As inhibition of P uptake by the plankton. Under winter ice 40 micromoles per liter arsenate or arsenite inhibited microbial degradation by 50%. Under aerobic conditions, arsenite was oxidized at the rate of two micromoles per liter per day. Summer rates were similar. Under anaerobic conditions arsenate was reduced at the rate of one micromole per liter per day. (Cassar-FRC)

SULFHYDROLASE ACTIVITY IN SEDIMENTS OF WINTERGREEN LAKE, KALAMAZOO COUNTY, MICHIGAN,
Michigan State Univ., Hickory Corners. W. K. Kellogg Biological Station.
G. M. King, and M. J. Klug.
Applied and Environmental Microbiology, Vol 39, No 5, p 950-956, May, 1980. 4 Fig, 3 Tab, 17 Ref.

Descriptors: Sediments, Lakes, *Sulfates, Enzymes, *Wintergreen Lake, *Michigan, Hypolimnion, Sulfides, Oxidation, *Lake sediments.

An initial characterization of the ester sulfate cycle in anoxic sediments of Wintergreen Lake, Michigan, is presented. Significant levels of sulfhydrolase activity were found in littoral, transition, and profundal sediment samples. Rates of sulfate formation suggest that the sulfhydrolase system would represent a major source of sulfate within these sediments. Sulfate formed by ester sulfate hydrolysis can support dissimilatory sulfate reduction as indicated by the incorporation of S-35 from labeled sodium dodecyl sulfate into S-35 labeled hydrogen sulfide. Sulfhydrolase activity varied with sediment depth, was greatest in the littoral zone, and was sensitive to the presence of oxygen. Estimations of ester sulfate concentrations in sediments revealed large quantities of ester sulfate. Both total sulfur and ester sulfate concentrations varied with the sediment type and were two to three orders of magnitude greater than the inorganic sulfur concentration. (Baker-FRC)

COMPARISON OF IN SITU AND IN VITRO RATES OF METHANE RELEASE IN FRESHWATER SEDIMENTS,
Michigan Univ., Ann Arbor. Dept. of Environmental and Industrial Health.
C. A. Kelly, and D. P. Chynoweth.
Applied and Environmental Microbiology, Vol 40, No 2, p 287-293, August, 1980. 2 Fig, 4 Tab, 26 Ref.

Descriptors: *Sediments, *Methane, Lakes, Microbial degradation, Natural waters, Seasonal variations, Lake sediments, Comparison studies.

A study was made of anaerobic lake sediment incubated in vitro for its ability to mimic natural in situ sediment activities, using rate of methane production for the comparison. Two lakes with different rates and seasonal patterns of methanogenic activity were compared. During the study 82 cores were taken and 200 individual sections were incubated. There was good agreement between rates of in situ methane release and initial rates of production measured in vitro in surface sediment. The evidence indicated that it is the in situ surface sediment methane production which is primarily responsible for maintaining in situ methane release, and thus the above agreement was what was expected if surface in situ activity was maintained in vitro. When deeper sediment was investigated, the sum of in vitro rates from 0 to 20 cm was much higher than in situ release rates and would have resulted in an impossibly high volume of gas. The extra gas could not have been stored within the sediments. It was concluded that the in situ methanogenic activity of the 0 to 3 cm anaerobic surface sediments could be preserved during removal and laboratory incubation. However, similar treatment of deeper sediment appeared to stimulate methanogenic activity. (Baker-FRC)

FACTORS AFFECTING PHOSPHORUS RELEASE FROM INTACT LAKE SEDIMENT CORES,
Wisconsin Univ.-Madison. Water Chemistry Lab.
G. C. Holdren, Jr., and D. E. Armstrong.
Environmental Science and Technology, Vol 14, No 1, p 79-87, January, 1980. 7 Fig, 6 Tab, 37 Ref.

Descriptors: *Sediments, *Phosphorus, *Lakes, *Lake sediments, Limnology, Lake morphology, Lake stages, Epilimnion, Temperature effects, Eutrophication, Wisconsin, Oxidation-reduction potential.

This investigation considered the effects of mixing, redox potential, temperature, bioturbation, and sediment type in lakes on phosphorus release. Since phosphorus release into anoxic hypolimnetic waters can be approximated by diffusion models, only epilimnetic sediments were investigated. Intact sediment cores from epilimnetic areas of four Wisconsin lakes were incubated in the laboratory to determine the effects of various environmental parameters on sediment phosphorus release. Bioturbation was found to have the greatest effect on phosphorus release rates. Raising the temperature or lowering oxygen concentrations in the overlying water also led to increased release rates, while suspension of sediment and lowering the temperature removed phosphorus from the water column. Sediment type affected the relative importance of differing incubation conditions, with redox potential having more effect on noncalcareous sediments and temperature having greater effect on calcareous sediments. The results indicate that epilimnetic sediments could contribute significant amounts of inorganic phosphorus to the overlying water in some lakes. (Baker-FRC)

LIGNOCELLULOSE MINERALIZATION BY ARCTIC LAKE SEDIMENTS IN RESPONSE TO NUTRIENT MANIPULATION,
Cincinnati Univ., OH. Dept. of Biological Sciences.
T. W. Federle, and J. R. Vestal.
Applied and Environmental Microbiology, Vol 40, No 1, p 32-39, July, 1980. 6 Fig, 2 Tab, 22 Ref.

Descriptors: *Mineralization, *Arctic zone, *Lake sediments, Lignocellulose, Decomposition, Decomposing organic matter, Deterioration, Degradation, *Nutrients, Nitrogen, Phosphorus, Cellulose, Lignin.

Mineralization of specifically labeled C-14-lignocelluloses by sediments from a remote arctic lake was examined with regard to nutrient concentration and other environmental factors. The mineralizations of the cellulose and lignin components of lignocellulose were found to respond differently to manipulation of nitrogen and phosphorus levels. This suggests that nutrient concentrations, in addition to the relative recalcitrance of the two compounds, may be important in explaining the increased proportion of lignin to cellulose in decomposing litter. Mineralization was measured by quantifying the amount of labeled carbon dioxide released from the substrates. Nitrogen, and to a greater degree, phosphorus additions enhanced the mineralization of white pine cellulose during the summer of 1978. Nitrogen and phosphorus together had no cumulative effect. During the summer of 1979 nitrogen or phosphorus alone had only a slight stimulatory effect on the mineralization of a sedge cellulose, but together they had a dramatic effect. These differences were attributed to yearly variations in the nutrient availability within the lake. (Baker-FRC)

OCCURRENCE OF APHANOMYCES OVIDESTRUENS, A FUNGUS PARASITIC ON COPEPODS, IN TWO EUTROPHIC LAKES,
Otago Univ., Dunedin (New Zealand). Dept. of Zoology.
C. W. Burns.
New Zealand Journal of Marine and Freshwater Research, Vol 14, No 1, p 23-29, 1980. 3 Fig, 1 Tab, 13 Ref.

Descriptors: *Trophic level, *Lakes, *Distribution patterns, Fungi, *Aquatic fungi, Eutrophication, Animal parasites, Parasitism, Predation, Copepods, Aquatic life, Animal diseases, Reproduction, Population dynamics, *Eutrophic lakes, *New Zealand.

The occurrence of Aphanomyces ovidestruens on a freshwater calanoid copepod, Boeckella dilatata Sars, from two lakes in New Zealand is reported. The location and form of the asexual zoospores, oogonia, antheridia, and infection hyphae of the fungus on B. dilatata demonstrated some differences from the description of Aphanomyces ovidestruens. The infection hyphae on B. dilatata did not swell distally into bulbous appressoria, but rather tapered, sometimes accompanied by small constrictions, before branching into fine hyphae in the eggs of the host. The oogonia and oospores were typically larger in the fungus on B. dilatata than in that of Diaptomus gracilis. The oogonial walls of A. ovidestruens on B. dilatata were usually conspicuously roughened, often to the extent of being ornamented with tubercles or spines up to 5 micrometers long. The incidence of infection in the populations of B. dilatata was different in the two lakes and varied throughout the study. (Baker-FRC)

THE PREDICTION OF LACUSTRINE PHYTOPLANKTON DIVERSITY,
McGill Univ., Montreal (Quebec). Dept. of Biology.
B. D. LaZerte, and S. Watson.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 5, p 524-534, May, 1981. 7 Fig, 4 Tab, 37 Ref.

Descriptors: *Phytoplankton, *Species diversity, *Biomass, Lakes, *Lake Memphremagog, Quebec, Algae, Species composition, *Taxonomy, Prediction, Sampling.

Lake Memphremagog, Quebec, was the site of a two year study performed to test the hypothesis that total phytoplankton biomass can predict phytoplankton community structure independent of its taxonomic composition. A range of diversity numbers, based on proportional biomass, was calculated for each of 133 samples. Biomass was a good predictor of species evenness (relative distribution of biomass) but not species richness (number of species present) provided that counts were rarefied to a fixed and ideally large size. The method is not applicable to under-ice communities and to the extremely low biomass communities immediately after ice-out. Species richness is mainly dependent on season and changes in taxonomic composition. (Cassar-FRC)

PREDICTION OF TOTAL PHOSPHORUS CONCENTRATIONS, CHLOROPHYLL A, AND SECCHI DEPTHS IN NATURAL AND ARTIFICIAL LAKES,
Iowa State Univ., Ames. Dept. of Animal Ecology.
D. E. Canfield, Jr., and R. W. Bachmann.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 4, p 414-423, April, 1981. 4 Fig, 5 Tab, 27 Ref. OWRT-A-063-IA(2).

Descriptors: *Lakes, *Phosphorus compounds, *Prediction, Model studies, Nutrients, Chlorophyll a, Secchi disks, Algae, Transparency, Eutrophication, Sediments, Lake sediments, Sedimentation rates, Artificial lakes, Natural waters.

A model for predicting total phosphorus was developed and tested using data on 704 natural and artificial lakes. It estimates P concentrations over a wide range of lake types at a 95% confidence interval of 31-288% of the calculated total P concentration. Total P concentrations are predicted equally well in natural and artificial lakes, but predictions of algal density as measured by Secchi disc and chlorophyll a concentrations are more reliable for natural lakes than for artificial lakes. This may be a result of non-algal turbidity. This model should be applicable to most lakes within the temperature region of the U.S. and southern Canada except for lakes in closed basins or bays within lakes. (Cassar-FRC)

POSTDEPOSITIONAL MOBILITY OF PHOSPHORUS IN LAKE SEDIMENTS,
McGill University, Montreal (Quebec). Dept. of Biology.
R. Carignan, and R. J. Flett.
Limnology and Oceanography, Vol 26, No 2, p 361-366, March, 1981. 7 Fig, 25 Ref.

Descriptors: *Phosphorus, *Lake sediments, *Migration, Lakes, Sediments, Path of pollutants, Sedimentation, Nutrients, Lake Memphremagog, Quebec, Sediment-water interfaces, Deposition.

Phosphorus in sediments of Lake Memphremagog, Quebec, migrated upward and accumulated near the sediment-water interface in the 2-6 cm layer, as defined by constant Pb210 activity. In this layer, total phosphorus ranged from 2700 to 3300 micrograms per g, whereas the upper 2 cm contained about 2200 micrograms per g and the 7-18 cm layers 1300-1900 micrograms per g. In a 5-week experiment, homogenized sediment was placed in water in an aquarium with aeration and homogeneous mixing. Core samples showed that the total P concentration of the top 1 cm section was 1400 micrograms per g; the 1-2 cm layer was slightly depleted in P, 1100 micrograms per g; and the remainder of the column, 1200 micrograms per g. Interstitial P decreased to 0 at the surface from 1250-1350 micrograms per g in the rest of the profile. Soluble reactive P concentrations were fairly constant, near 200-300 micrograms per g throughout most of the profile, with a sudden increase in the top 1 cm and a slight decrease in the 1-2 cm layer. Iron concentrations behaved in a similar manner. This strongly suggests that upward P and Fe movements were induced by diffusion of interstitial P and Fe along a concentration gradient generated by precipitation in the oxidized surface layer of the sediments. Similar gradients were seen in nondisturbed sediments, indicating that this upward migration operates also under natural conditions. The remobilized P appears to be isotopically exchangeable (or mobile) under anaerobic conditions. Therefore, the total P levels in surface sediments have no relation to the currently sedimenting material, and P levels in the sediment layers may give a false historical P loading profile or P sedimentation rates. (Cassar-FRC)

THE IMPORTANCE OF REGENERATED NITROGEN TO PHYTOPLANKTON PRODUCTIVITY IN A SUBALPINE LAKE,
California Univ., Davis. Div. of Environmental Studies.
R. P. Axler, G. W. Redfield, and C. R. Goldman.
Ecology, Vol 62, No 2, p 345-354, April, 1981. 3 Fig, 4 Tab, 45 Ref.

Descriptors: *Nitrogen, *Phytoplankton, Mineralization, California, Alpine regions, Cold regions, Lakes, Nutrients.

The rate of ammonium regeneration due to zooplankton excretion and microbial mineralization processes were studied in relation to the rate of inorganic nitrogen assimilation by phytoplankton in epilimnetic water. The euphotic zone of dimictic, meso-oligotrophic Castle Lake is characterized by a rapid depletion of both nitrate and ammonium soon after spring thaw. External inputs of nitrogen are minimal during this period of time, and levels of inorganic nitrogen remain low until fall overturn. The rate of ammonium assimilation was high relative to nitrate assimilation, and was significantly correlated with the rate of ammonium regeneration. The importance of this rapid turnover of nitrogen to phytoplankton growth is consistent with the results of previous Castle Lake studies and with the current conceptual model of primary production in the mixed layer of nitrogen-deficient marine ecosystems. (Baker-FRC)

SEASONAL PARTICLE-SIZE SELECTION BY DIAPTOMUS SICILIS IN OFFSHORE LAKE MICHIGAN,
National Atmospheric and Oceanic Administration, Ann Arbor, Mich. Great Lakes Environmental Research Lab.
H. A. Vanderploeg.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 5, p 504-517, May, 1981. 3 Fig, 2 Tab, 52 Ref.

Descriptors: *Food habits, *Copepods, *Particle size, Lakes, Invertebrates, Aquatic animals, *Lake Michigan, Particle shape, Zooplankton, Diaptomus, Seston.

Diaptomus sicilis, a copepod abundant in the Laurentian Great Lakes, showed a relatively invariant pattern of particle-size selection in 23 separate feeding experiments conducted from spring through fall over a 2-year period. This pattern persisted for different feeding rates under varying conditions of particle-size spectrum shape, abundance and food quality of particles, and temperature. In one case, where the curve of filtering efficiency vs. particle size differed from the other curves, grazer-produced particles and/or elongated particles dominated the seston. The invariant selection is not inconsistent with both filtering and raptorial modes of feeding operating simultaneously. Evidence indicates that these organisms feed in a strong passive-mechanical filtering mode that may be supplemented by a raptorial mode that selects large particles of high food quality. (Cassar-FRC)

REDUCTION OF SULFUR COMPOUNDS IN THE SEDIMENTS OF A EUTROPHIC LAKE BASIN,
Michigan State Univ., Hickory Corners. W. K. Kellogg Biological Station.
R. L. Smith, and M. J. Klug.
Applied and Environmental Microbiology, Vol 41, No 5, p 1230-1237, May, 1981. 8 Fig, 1 Tab, 22 Ref.

Descriptors: *Sulfur compounds, *Eutrophic lakes, *Lake sediments, Lakes, Sediments, Lake basins, Chemical reduction, Metabolism, Nutrients, Sulfur, Sulfates, Isotopic tracers.

The significance of sulfate reduction in sediments of inland waters, and especially of fresh water lakes, has not been as extensively characterized as that of marine systems. The distribution of natural sulfur substances (SO4 (2-), H2S, S(0), acid-volatile sulfide, and total sulfur) in the sediments and overlying water column of a eutrophic fresh water lake and the occurrence of significant rates of sulfate reduction in this environment were investigated. Low concentrations of sulfate relative to those of acid-volatile sulfide and total sulfur and a decrease in total sulfur with sediment depth implied that the contribution of dissimilatory sulfur reduction to H2S production was relatively minor. Kinetic experiments with 35S demonstrated an apparent Km of 0.068 mmol of SO4(2-) reduced per liter of sediment per day. Tracer experiments with 35S indicated an average turnover time of the sediment sulfate pool of 1.5 hours. A sediment depth profile to 15 centimeters demonstrated a total sulfate reduction of 15.3 mmol of sulfate reduced per square meter per day, corresponding to a mineralization of 30% of the particulate organic matter entering the sediment. Reduction of 35S(0) occurred at a slower rate. Although these sediments contained low concentrations of oxidized inorganic compounds, the rates of sulfate reduction were high. These results indicate that this reduction can be

important in the anaerobic mineralization of organic carbon. (Carroll-FRC)

SOYROOT - A DYNAMIC MODEL OF SOYBEAN ROOT GROWTH AND WATER UPTAKE,
Punjab Agricultural Univ., Ludiana (India). Dept. of Soil and Water Engineering.
N. K. Narda, and R. B. Curry.
Transactions of the ASAE, Vol 24, No 3, p 651-656, 662, May/June, 1981. 5 Fig, 2 Tab, 31 Ref.

Descriptors: *Soybeans, *Mathematical models, *Growth, Growth rates, Roots, *Root development, *Moisture uptake, Soil-water-plant relationships, Carbohydrates.

SOYROOT, a dynamic model of soybean root growth, was developed from root growth attributes measured in laboratory and field studies, combined with simulated carbohydrate available for root growth. The model was based on evidence that root length provides a better correlation with water uptake by the plant root system than does root weight or number of roots. It consists of a root growth submodel and a macroscopic model of water uptake. Three simulation runs of the model were made using 1978 climatological data for Wooster, Ohio. The SOYMOD/OARDC model when coupled with the SOYROOT model responded to changes in soil moisture content predicted by the macroscopic model. The macroscopic model predicted soil moisture content reasonably well. The SOYROOT model is a first approximation and must be further reviewed and validated. (Small-FRC)

EFFECT OF IRRIGATION AND TREE DENSITY ON PEACH PRODUCTION,
Department of Agriculture, Harrow (Ontario).
R. E. C. Layne, C. S. Tan, and J. M. Fulton.
Journal of the American Society for Horticultural Science, Vol 106, No 2, p 151-156, March, 1981. 2 Fig, 2 Tab, 22 Ref.

Descriptors: *Crop yield, *Irrigation effects, *Peaches, Orchards, Plant growth, Fruit crops, Trees, Harrow, Ontario, Water stress.

Three irrigation regimes (no irrigation, 25% and 50% available soil moisture, ASM) and three tree planting densities (266, 358, and 536 trees per hectare) were studied in a peach (Prunus persica L. Batsch cv. Harken/Siberian C) orchard planted near Harrow, Ontario, in 1973. The 25% ASM plots were irrigated about four times yearly and the 50% plots, about 12 times per year. The best treatment was the highest tree density and 50% ASM, which increased fruit yields up to 99.5%. Irrigation at 50% ASM increased yields in the first five years of production up to 9.7%. No irrigation and the highest tree density increased yields up to 74.6%. Tree growth in irrigated plots was significantly greater than in unirrigated plots during the early years, 1974 and 1975, when the tree roots were near the surface. From 1976 to 1979 there was no significant difference. Tree growth was reduced by increasing tree density with the exception of 50% ASM and the highest tree density. Fruit size (proportion of marketable fruit) was increased by irrigation and little affected by tree density. There was no significant effect of irrigation or tree density on disease susceptibility or raw product fruit quality. (Cassar-FRC)

EFFECTS OF SOIL WATER REGIME AND NITROGEN FORM ON BLOSSOM-END ROT, YIELD, WATER RELATIONS, AND ELEMENTAL COMPOSITION OF TOMATO,
Missouri Univ., Columbia.
W. G. Pill, and V. N. Lambeth.
Journal of the American Society for Horticultural Science, Vol 105, No 5, p 730-734, September, 1980. 8 Tab, 29 Ref.

Descriptors: *Plants, *Water stress, Water demand, Nutrients, Calcium, Soil water, Potassium, Magnesium, Fertilization, *Nitrogen, *Soil-water-plant relationships, *Blossom-end rot.

A study was conducted to elucidate the interactive effects of soil water regime with NO3-N and NH4-N fertilization on blossom-end rot (BER) incidence and on plant ion concentrations and water stress. Seeds of Missouri breeding line 76-1-60-8 tomato, a relatively BER-susceptible line, were sown in vermiculite. Thirty-six 3-week-old seedlings were transplanted into individual 20 cm clay pots. Eight applications of NO3-N or NH4-N at 28 meq per pot were made at 5 day intervals. Under the two wettest soil water regimes, NH4-N compared to NO3-N fertilization reduced total and mean fruit number, whereas no difference was found under the driest regime. Incidence and severity of BER were increased by NH4 nutrition and by decreasing soil water potential. Decreasing soil water potential did not influence leaf Ca, Mg, or K concentrations, but it did decrease fruit concentration of these ions. At any soil water regime, NH4 fertilization decreased leaf Ca and Mg concentration, but generally increased leaf K and fruit Ca, Mg, and K concentrations. Since leaf diffusive resistance values increased with decreasing soil water potential, but were unaffected by N form, the lower overall transpiration and areal transpiration rates under NH4-N might be explained by increased non-leaf resistances to water flux and/or by reduced soil-plant water potential gradients. ENVIRONMENTAL RESOURCES AND RESTRAINTS TO AGRICULTURAL PRODUCTION IN A MEDITERRANEAN-TYPE ENVIRONMENT,
University of New England, Armidale (Australia). Dept. of Agronomy and Soil Science.
R. C. G. Smith, and H. C. Harris.
Plant and Soil, Vol 58, No 1-3, p 31-57, 1981. 17 Fig, 3 Tab, 37 Ref.

Descriptors: *Crop production, *Rainfall impact, *Soil water, Rainfall intensity, Rainfall rate, Precipitation, Agriculture, *Mediterranean, Semiarid climates, Arid climates, Soil-water-plant relationships, Crop yield, Model studies.

A dynamic model of a wheat crop was developed to analyze climatic data from a Mediterranean type environment in an effort to assess the relative importance of various environmental constraints. The environmental variables considered included day length, temperature, frost, solar radiation, wind, humidity, rainfall, and soil. This study used climatic data from a typical lowland site at Aleppo, Syria, where sowing generally is accomplished between mid-November and mid-December. The potential growing season, which is the time between the point at which continuous growth begins and the time it must cease because of the shortage of soil water, is determined by the interaction between climate, crop water use, and stored soil water. Annual rainfall during the growing season at Aleppo over a 14-year period varied from 113 millimeters to 453 millimeters and was positively correlated with potential growing season. Soil depth and texture are the major factors affecting the storage of water. The daily soil water balance for 12 years was simulated in order to analyze the variability of the distribution of soil water with depth and over time. Fallowing can be used to even out the availability of soil water from year to year. An evaluation of the crop water use and of the longer term effects of any increase in water use on the soil water carryover and variability of the system should be conducted prior to any change in the crops used in rotations. The ideal wheat variety for this climate would be one which would give modest yields in dry years but which would be yield-responsive in wetter years. (Carroll-FRC)

EFFECTS OF WATER REGIME ON GROWTH, YIELD, AND NITROGEN UPTAKE OF RICE,
International Rice Research Inst. Los Banos (Philippines).
C. S. Khind, and F. N. Ponnamperuma.
Plant and Soil, Vol 59, No 2, p 287-298, 1981. 6 Fig, 3 Tab, 14 Ref.

Descriptors: *Flood irrigation, *Rice, *Denitrification, Crop production, *Crop yield, *Wetlands, Nitrogen removal, Irrigation practices, Irrigation.

About 40% of the world's wetland rice area is rainfed and therefore is not assured of a water supply for continuous soil submergence, often resulting in alternate flooding and drying during the crop season. Since severe nitrogen losses through nitrification-denitrification are caused by alternate wetting and drying of soils, this process is believed to be an important pathway of nitrogen loss in rainfed wetland rice fields. A greenhouse experiment and two field experiments were conducted to investigate the effects of water regime on the performance of rice. The greenhouse experiment involved four water regimes (continuous flooding and soil drying for 16 days followed by reflooding, with drying beginning 2, 5, and 8 weeks after transplanting), four soils, and 0 and 100 milligrams of nitrogen per kilogram. The redox potentials of all soils were raised above the aerobic threshold by soil drying. While none of the soil drying regimes adversely affected soil high in nitrogen, adverse effects in the soil low in nitrogen were noted when soil drying occurred 2 and 5 weeks after transplanting. The field experiments tested the effects of three water regimes (continuous flooding, alternate drying and flooding every 2 weeks, and soil drying for 2 weeks at 6 weeks after transplanting followed by reflooding) and nitrogen concentrations of 1, 50, 100, and 150 kilograms per hectare on a nearly neutral clay soil during two growing seasons. None of the soil drying treatments resulted in decreased growth, yield, or nitrogen uptake by rice at any level of nitrogen in either growing season. Denitrification was not possible on reflooding since nitrate was absent after soil drying. These results indicate that loss of nitrogen due to alternate flooding and drying of soils carrying an established rice crop may not be appreciable, especially if the soil is high in nitrogen. A MODEL OF NATURAL AND MAN-INDUCED CHANGES IN OPEN FRESHWATER WETLANDS ON THE MASSACHUSETTS COASTAL PLAIN,
Massachusetts Univ., Amherst. Dept. of Forestry and Wildlife Management.
J. S. Larson, A. J. Mueller, and W. P. MacConnell.
Journal of Applied Ecology, Vol 17, No 3, p 667-673, December, 1980. 1 Fig, 2 Tab, 10 Ref. OWRT-A-121-MASS.(2), 14-34-0001-9023.

Descriptors: *Wetlands, *Succession, *Vegetation, Marshes, Water policy, *Massachusetts, Bogs, Freshwater marshes, Agriculture, Shallow water, Construction, Road construction, Aquatic plants, Land use, Bristol, Environmental effects.

Aerial photography and cover maps were used to measure changes in open freshwater wetlands (not including wooded wetlands) in Bristol, Massachusetts, between 1951 and 1971. Nearly half of the 3958.9 hectare area showed changes in vegetation class. Over 900 hectares of wetlands were lost during the 20-year period. Natural succession pro-

duced more changes in vegetation (1485.2 hectares) than man-induced causes (total 560.0 hectares). Agriculture (82.9 hectares), cranberry culture (82.9 hectares), highway construction (84.5 hectares), and reservoirs and impoundments (103.1 hectares) were the leading man-induced causes of wetland changes. Although northeast U.S. wetlands are considered relatively stable, this data suggests a dynamic process. The main sequence moves from open water, through vegetated open water, deep marsh, shallow marsh, shrub swamp, to wooded wetland. Branches from this main sequence include dead woody deep marsh, cranberry bog, seasonally flooded flat, and meadow. (Cassar-FRC)

TWO-DIMENSIONAL LINEARIZED MOISTURE FLOW WITH WATER EXTRACTION,
Arizona Univ., Tucson. Dept. of Soils, Water and Engineering.
A. W. Warrick, and D. O. Lomen.
Journal of Hydrology, Vol 49, No 3/4, p 235-246, 1981. 4 Fig, 12 Ref. OWRT-B-064-ARIZ(6).

Descriptors: *Moisture, *Sinks, Flow velocity, Fluctuations, Plant water potential, Hydrology, Soil-water-plant relationships, Soil water.

Analytical solutions for two-dimensional sources are presented, with the flow into the system balanced by space-distributed sink functions and flow out from the boundaries. The generalized solutions are presented for three types of surface boundary conditions: specified flux, specified matrix flux potential and flux proportional to the matrix flux potential. The first case is appropriate for trickle irrigation, the second for specified surface moisture or pressure head conditions, and the last analogous to evaporative conditions. Additional sub-surface line-sources can be combined with any of these solutions. The specific numerical results obtained all show similarities to line-sources of the same net strength, suggesting that a good first approximation can be found by assuming a source only equal to the net addition of water. The maximum error due to the approximation would be in the region close to the source, with the error damped out over relatively short distances. (Baker-FRC)

VEGETATION AND NUTRIENT STATUS OF NORTHERN MICHIGAN BOGS AND CONIFER SWAMPS WITH A COMPARISON TO FENS,
Michigan Univ., Pellston. Biological Station.
C. R. Schwintzer.
Canadian Journal of Botany, Vol 59, No 5, p 842-853, May, 1981. 5 Tab, 53 Ref.

Descriptors: *Bogs, *Fens, *Swamps, Peat bogs, *Nutrients, Wetlands, Vegetation, Succession, Hydrogen ion concentration, Water chemistry, Classification, *Michigan.

Information was obtained about the vegetation and telluric nutrient status of bogs and conifer swamps, comparable to that already available for fens. Also, bogs, fens, and conifer swamps were compared with respect to these features. The six bogs studied were characterized by well-developed field and bryophyte layers and strongly acid waters with very low Ca and Mg. The most prevalent plants were Chamaedaphne calyculata and Carex oligosperma of the field-layer plants and Sphagnum of the bryophyte layer. The four conifer swamps studied were characterized by well-developed tree and field layers and circumneutral waters of pH 7 to 7.4 with moderate to high Ca, Mg and alkalinity. The tree layer was dominated by Thuja occidentalis, while the most prevalent field plants were Mitella nuda, Abies balsamea, and Maianthemum canadense. Bogs, conifer swamps, and fens were related successionally but had different floristics, species density, proportion of evergreen species, role of symbiotic nitrogen fixing species, role of Sphagnum, and water chemistry. Bogs can be differentiated from conifer swamps and fens on the basis of nutrient status, which is dependent upon the degree of telluric water influence in rooting zones. Thus, these three types of wetlands should not be lumped together in the general category of bogs but should be considered separately. (Small-FRC)

2J. Erosion and Sedimentation

EROSION AND SEDIMENTATION IN THE KENAI RIVER, ALASKA,
Geological Survey, Laguna Niguel, CA. Water Resources Div.
K. M. Scott.
Geological Survey Open-File Report 81-219, 1981. 116 p, 19 Fig, 5 Tab, 53 Ref.

Descriptors: *Streams, *Channel erosion, *Bank erosion, *Sedimentation, Watersheds, Flow characteristics, Snowmelt, Floods, Bed load, Gravel, Vegetation effects, Fisheries, Salmon, Hydrographs, Aerial photography, *Alaska, *Kenai River.

The Kenai River is the most important freshwater fishery in Alaska. The flow regime is characterized by high summer flow of glacial meltwater and periodic flooding caused by sudden releases of glacier-dammed lakes in the headwaters. Every part of the stream is a known or potential salmon-spawning site. The stream channel is underfit, attributed to regional glacial recession and drainage changes, and locally is entrenched in response to geologically recent changes in base level. Throughout the central section of the river the channel is armored, a condition with implications for the ability of this section of channel to support the spawning and rearing of salmon. The entrenched section of the channel has been stable since 1951. Bank erosion is active both upstream and downstream from the entrenched channel, however. Although erosion rates have been generally constant since 1951, evidence suggests a possible recent decrease in bank stability that may be related to changes in river use. As population and recreation use increases, development can pose a hazard to the productivity of the stream through increased suspended-sediment concentration resulting directly from construction and, with greater potential for long-term impact, indirectly from bank erosion. A short-term hazard to both stream and developments is the cutoff of meander loops, the risk of which is increased by canals and boat slips cut in the surface layer of cohesive, erosion-resistant sediment on the flood plain within nonentrenched meander loops. A long-term hazard is an increase in bank erosion rates resulting from loss of vegetation on the high (up to 70 feet) cutbanks of entrenched and partially entrenched sections. (USGS)

DEPOSITION OF RIVERBORNE ORGANIC CARBON IN FLOODPLAIN WETLANDS AND DELTAS,
Oak Ridge National Lab., TN. Environmental Sciences Div.
P. J. Mulholland.
Available from the National Technical Information Service, Springfield, VA as CONF-8009140, Price codes: A18 in paper copy, A01 in microfiche. In: Flux of Organic Carbon by Rivers to the Oceans, Report of a Workshop, Woods Hole, MA, Sept 21-25, 1980, Dept. of Energy Report CONF-8009140, April 1981. p 142-172, 3 Fig, 2 Tab, 32 Ref.

Descriptors: *Organic carbon, *Flood plains, *Sediment distribution, *Deposition, Sedimentation, *Wetlands, Deltas, Sediment transport, Oxidation, Particulate matter, Reservoirs, Drainage, Channeling.

Interaction between rivers and floodplain wetlands generally results in a net annual deposition of riverborne sediment and particulate organic carbon of up to 100 g C per sq m over large wetland areas. Some of this material is certainly oxidized, but a large part of it probably escapes complete oxidation because of the lack of available oxygen. Global deposition of riverborne organic carbon in floodplain wetlands is at least 6% of total river flux, and probably higher. Some of man's activities, such as channelization and wetland drainage, are reducing the total area of floodplain wetland receiving river inputs. However, this reduction may be offset by increased erosion and subsequent floodplain deposition of organic carbon in less-developed regions. Increased construction of impoundments is increasing deposition and preservation of organic carbon in inland sediments. Land disturbance and agriculture increase soil erosion and result in large amounts of sediment deposition in the channels and floodplains of smaller streams and rivers. Assuming that the rates of formation of the world's major river deltas have been uniform over the past 12,000 years, organic carbon accumulation in these systems has been about 0.6 X 10 to the 15th power gC/yr. SECONDARY FLOW, SHEAR STRESS AND SEDIMENT TRANSPORT,
Pittsburgh Univ., PA. Dept. of Civil Engineering.
C-L. Chiu, and D. E. Hsiung.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY7, p 879-898, July, 1981. 9 Fig, 8 Ref.

Descriptors: *Open channel flow, *Shear stress, *Sediment transport, Model studies, Channel flow, Flow characteristics, Flow velocity, Flow pattern, Water conveyance, Alluvial channels.

Explicit links were established among interacting variables in open channel flows, such as the distribution of primary flow velocity, channel cross section, discharge rate, secondary flow, shear stress distribution, and sediment concentration. Data from the Rio Grande Conveyance, Bernardo, New Mexico, were used in the development of the relationships. A shear formula calculates the shear stress in the flow and along the bottom and side walls of alluvial channels. The geometric shape of boundary shear distribution computed along the channel bottom was similar to that of measured channel bottom, indicating a direct correlation between the boundary shear and the scour on the channel bed. The secondary flow affects sediment transport directly (convection) and indirectly (diffusion). The main parts of the mechanism governing sediment concentration are gravity, diffusion, and secondary flow. (Cassar-FRC)

ERODIBILITY OF STREAMBANK MATERIALS OF LOW COHESION,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
E. H. Grissinger, W. C. Little, and J. B. Murphey.
Transactions of the ASAE, Vol 24, No 3, p 624-630, May/June, 1981. 6 Fig, 2 Tab, 9 Ref.

Descriptors: *Stream banks, *Soil erosion, *Cohesion, Soil types, Clays, Erosion, Wetting, Shear stress, Erosion rates, Particle size, Flumes.

The stability of fine grained streambank materials was evaluated for materials with plasticity index values of less than 15. Erosion rates of undisturbed channel bank materials were determined in the field with a portable flume. Measured erosion rates were sizable, and two erosive forces were identified. Excessive erosion occurred in samples that were relatively dry before testing, probably as a result of the detaching effect of wetting. Erosion in wet samples was dependent upon bed shear stress. Clay content was correlated significantly with the shear stress-dependent erosion rates, while maximum noneroding pinhole velocities correlated significantly with the same erosion rates for samples that had no limiting morphological characteristics. The significance of sample morphology was scale dependent and varied with the size of the test sample in relation to the size of the morphological components. (Small-FRC)
W82-00136

EFFECT OF CROP RESIDUE ON SOIL LOSS FROM CONTINUOUS ROW CROPPING,
Science and Education Administration, Ames, IA. Agriculture and Home Economics Experimental Station.
J. M. Laflen, and T. S. Colvin.
Transactions of the ASAE, Vol 24, No 3, p 605-609, May/June, 1981. 3 Fig, 3 Tab, 13 Ref.

Descriptors: *Soil erosion, *Crop production, *Cultivated lands, Agriculture, Farms, Soil types, Slopes, Rainfall simulators, *Experimental farms.

Relative soil losses as affected by crop residue were evaluated using a rainfall simulator for several combinations of crop rotations, tillage systems, and canopy levels at two Iowa locations. Tillage treatments were conventional, reduced, and no-till, and the statistical design was a randomized complete block with two replicates. Crop canopy, kind of residue, and crop rotations had little effect on derived mulch factor-crop residue relationships, though this relationship was different at the two sites. The locational differences were apparently due to differences in slopes and/or soils. They can be explained on the basis of sediment transport, sedimentation theory, and size distributions of eroded material. Thus, presently used soil erosion prediction methods for conservation tillage systems could be improved by including the interaction effects of crop residue, soil, and slope. (Small-FRC)

SEDIMENT TRANSPORT IN NORTON SOUND, ALASKA,
Geological Survey, Menlo Park, CA.
D. E. Drake, D. A. Cacchione, R. D. Muench, and C. H. Nelson.
Marine Geology, Vol 36, No 1/2, p 97-126, May, 1980. 16 Fig, 1 Tab, 20 Ref.

Descriptors: *Sediment transport, *Sounds, Tractive forces, Bays, Bights, *Yukon River, Rivers, Sand, Silt, Sediments, Silting, Norton Sound, *Alaska.

Temporal variations were monitored in bottom currents, pressure, and suspended matter concentrations within the major transport pathway of Yukon River suspended matter. The most significant transport occurs within advective currents flowing north across the outer part of the sound. The thickest accumulations of modern Yukon silt and very fine sand occur beneath this persistent current. Monitoring took place for 80 days during the summer of 1977 using a Geological Processes Bottom Environmental tripod system. Two distinctive periods of bottom flow and sediment transport were noted: an initial 59 days of fair-weather conditions, characterized by tidally dominated currents and relatively low, stable suspended-matter conditions; and a 21 day period during which several storms traversed the Northern Bering Sea, mean suspended-matter concentrations near the bottom increased by a factor of five, and the earlier tidal dominance was overshadowed by wind-driven and oscillatory wave-generated currents. Friction velocities at the monitoring site were generally subcritical during the fair-weather period. The data suggest that very fine sand constituting about 50% of the sediment on the outer part of the Yukon prodelta is transported during a few late-summer and fall storms each year. Suspended-matter transport during the storms in September 1977 was equal to four months of fair-weather transport. (Baker-FRC)

ESTIMATING THE PHYSICAL CARRYING CAPACITY OF RECREATION AREAS: A RATIONALE FOR APPLICATION OF THE UNIVERSAL SOIL LOSS EQUATION,
Maryland Univ., College Park. Dept. of Recreation.
F. R. Kuss, and J. M. Morgan, III.
Journal of Soil and Water Conservation, Vol 35, No 2, p 87-89, March/April, 1980. 2 Tab, 21 Ref.

Descriptors: *Recreation facilities, *Soil management, Vegetation, Planning, Erosion, Soil conservation, Universal Soil Loss Equation, Land use, Soil erosion.

The Universal Soil Loss Equation was used to predict the physical carrying capacity of recreational areas. The soil loss tolerance factor (T) was substituted for the average annual soil loss per unit area (A). T represents the maximum rate of soil erosion that will permit the land's productivity to be sustained. Thus, T divided by the soil loss index becomes the maximum value of C (the vegetative cover and management factor) that an area can tolerate. Three picnic sites in the Patapsco Valley State Park, Maryland, were examined using the equation. The C values for the 3 sites were 0.009, 0.019, and 0.043, indicating that the first was a relatively sensitive area and should be zoned for limited use or scheduled for additional maintenance. Site 3 was relatively tolerant of recreational use. (Cassar-FRC)
W82-00274

SOLAR CYCLES AND EROSIONAL EVENTS ON THE NEW SOUTH WALES CENTRAL AND SOUTH COASTS,
Sydney Univ. (Australia).
B. Stevenson.
Search, Vol 11, No 4, p 117-118, April, 1980. 2 Fig, 12 Ref.

Descriptors: *Beach erosion, *Sunspots, *Weather patterns, Solar radiation, Erosion, Jetstreams, *New South Wales, Australia, Storms, Coasts.

Erosional events on Australia's New South Wales coast were related to periods of low sunspot activity in 1857, 1876, 1889, 1912, 1944-45, 1966-67, and 1974-75. A high pressure anomaly occurs in the southern Tasman region during July at the sunspot minima and ascending phase of the sunspot cycle. This condition represents enhanced blocking with a resulting increase in storm activity and coastal erosion. A likely intermediate agent is variation in jetstream activity over the east Australian continent, weaker jetstreams being associated with low sunspot activity. (Cassar-FRC)

RAINFALL INTENSITY-KINETIC ENERGY RELATIONSHIPS FOR SOIL LOSS PREDICTION,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Inst. of Earth Resources.
P. I. A. Kinnell.
Soil Science Society of America Journal, Vol 45, No 1, p 153-155, 1981. 2 Fig, 1 Tab, 11 Ref.

Descriptors: *Soil erosion, *Rainfall intensity, *Mathematical equations, Prediction, Erosion, Rainfall impact, Kinetic energy, Mathematical studies.

Soil erosion involves an expenditure of energy to detach soil material from the soil surface and to transport this detached material away from the eroding area. The kinetic energy expended by raindrops impacting with the soil surface accounts for a proportion of the energy required in the rainfall erosion process. Since the calculation of rainfall kinetic energies from drop-size data has demonstrated a high correlation between the rate of expenditure of rainfall kinetic energy and rainfall intensity when raindrops are traveling at or close to their terminal velocities, this relationship provides a means for the estimation of variations in rainfall kinetic energy in time and space. Application of three equations used to describe rainfall intensity-kinetic energy relations to data for Miami, Florida, and Zimbabwe (Rhodesia) demonstrated the limitations of these equations. The relationships between kinetic energy per unit quantity of rain (E sub RA) and rainfall intensity (I) at these two locations are best expressed by the equation E sub RA equals z (1 minus pe(-hI), where e is the base of natural logarithms and z, p, and h are empirical constants. It is suggested that this equation may provide the means by which reasonable estimates of rainfall kinetic energy can be derived in other geographic areas. (Carroll-FRC)
W82-00466

EFFECT OF MULCH RATE ON SOIL LOSS BY RAINDROP SPLASH,
California Univ., Davis. Dept. of Land, Air, and Water Resources.
M. J. Singer, Y. Matsuda, and J. Blackard.
Soil Science Society of America Journal, Vol 45, No 1, p 107-110, 1981. 3 Fig, 2 Tab, 14 Ref.

Descriptors: *Soil erosion, *Mulching, *Rain, Erosion control, Erosion, Rills, Rainfall simulators, Mathematical studies, Kinetic energy, Rain splash, Sediment transport.

Previous studies by the present authors had investigated the relationship between percent cover by oat straw, blue oak leaves, and redwood litter and soil loss under simulated rainfall. A likely explanation for the finding of a parabolic relationship rather than the expected linear relationship is the lack of splash measurements as part of the experiment. A total of 50 rainfall simulator events of 76 millimeters per hour intensity for 30 minutes were run to investigate the effect of oat straw on splash detachment and transport of soil. Soil available for transport by interrill flow is a function of soil detached by interrill flow, direct splash impact, and secondary splash impact. Soil transported by interrill flow and soil transported by rain splash were measured separately. Increases in straw mulch rate resulted in significant decreases in both soil transported by rain splash and soil transported by interrill flow. When straw mulch cover reached 96%, rain splash sediment transport was reduced to less than 8% of the bare soil rain splash transport and interrill flow transport was reduced to 24% of the bare soil rain-flow transport amount. Since there was no reduction in the interril flow, the reduction in interrill flow transport was entirely due to a reduction in raindrop splash detachment. A linear correlation was found between cover level and sediment transport by rain splash and interrill flow when both processes were considered. The effectiveness of cover as an erosion control technique results from reductions in both direct rain splash detachment and indirect rain splash effects. (Carroll-FRC)

EFFECTS OF SMALL AMOUNTS OF RESIDUE ON FURROW EROSION,
Science and Education Administration, Prosser, WA.
J. S. Aarstad, and D. E. Miller.
Soil Science Society of America Journal, Vol 45, No 1, p 116-118, 1981. 4 Tab, 9 Ref.

Descriptors: *Erosion control, *Soil erosion, *Organic matter, Erosion, Decomposing organic

matter, Turbidity, Agricultural runoff, Irrigation ditches, Sedimentation, Runoff, Furrow drainage.

Previous studies have demonstrated that preserving residue through reduced tillage may effectively control furrow erosion from irrigation. However, some tillage is desirable to incorporate fertilizers and herbicides and to prepare the seedbed. Since tillage destroys plant residues, this study was designed to determine whether or not small amounts of plant residue placed in irrigation furrows would decrease furrow erosion to tolerable levels. Studies conducted on a medium-textured soil with a 3% slope demonstrated that even the lowest residue rate, which consisted of a clump of straw placed every 2 meters down the furrow and was equivalent to about 60 kilograms per hectare on a total area basis, greatly reduced the sediment in and the turbidity of the runoff water. When 2.2 metric tons of straw per hectare was placed along the furrow, equivalent to about 0.4 metric tons per hectare on a total area basis, virtually all erosion was eliminated. Infiltration rates generally increased as the amount of residue in the furrow increased, causing a decrease in runoff velocity and sediment suspension. The highest residue rate reduced the turbidities of runoff water to less than those of the inflow water. These results indicate that limited tillage for herbicide incorporation and seedbed preparation can be performed while still leaving enough surface residue to control erosion. However, techniques and equipment for manipulation and placement of the residue after limited tillage need to be developed. (Carroll-FRC)

THE EFFECTS OF SURFACE SLATY FRAGMENTS ON SOIL EROSION BY WATER,
Southern Piedmont Conservation Research Center, Watkinsville, GA.
J. E. Box, Jr.
Soil Science Society of America Journal, Vol 45, No 1, p 111-116, 1981. 9 Fig, 5 Tab, 12 Ref.

Descriptors: *Surface runoff, *Soil erosion, *Soil properties, Rainfall, Slate, Erosion, Runoff, Rocks, Rainstorms, Mathematical studies, Mathematical equations, Soil types, Rainfall-runoff relationships, Mulching, *Slate Belt, *Southern Piedmont.

The Carolina Slate Belt, which extends from southern Virginia across the Carolinas and into Georgia, has shallow slaty soils in which slaty fragments make up between 5 and 40% of the surface soil weight. The effects of various amounts of slaty fragments on the surface on soil erosion and runoff were studied using Golston very slaty silt loam, Badin slaty silt loam, Georgeville silty clay loam, and a Georgeville loam. A rainulator was used to measure erosion and runoff from a 120-minute storm of 6.35 centimeters per hour. Photographs were used to determine the percent soil surface coverage by slaty fragments after each storm, which was found to range from 2.5 to 97%. Lots on which the soil had been sieved experienced soil loss rates which were about three to six times greater than the loss rates on natural plots. Doubling of the slaty fragments in the top 15 centimeters caused a soil loss rate lower than that of either the natural or the sieved plots. The relationship between soil loss ratio and percent coverage by slaty fragments was identical to that previously determined for plant residue mulching effects on soil loss ratio. An interim solution for predicting erosion on Slate Belt soils of the southern Piedmont which are subject to armoring by slaty fragments is proposed for use until sufficient data are available to adjust the K sub m factor or to add an armoring factor to the universal soil loss equation (USLE). Results from this study indicate that it may be possible to determine surface armoring after 30 minutes of intensive rainfall. (Carroll-FRC)

GULLY DEVELOPMENT IN THE DEEP LOESS HILLS REGION OF CENTRAL MISSOURI,
Missouri Univ., Columbia.
G. Roloff, J. M. Bradford, and C. L. Scrivner.
Soil Science Society of America Journal, Vol 45, No 1, p 119-123, 1981. 5 Fig, 3 Tab, 24 Ref.

Descriptors: *Gully erosion, *Loess, *Missouri, Soil strength, Soil erosion, Erosion, Overland flow, Slope stability, Geomorphology, Gullies, Stratigraphy, Soil properties.

Gullying is a frequent erosion phenomenon in the deep loess hills region of central Missouri, causing degradation of valuable farmland and increased sediment loadings in local streams. This study involved instrumentation of a small gully in a headslope position in loess over glacial till designed to monitor the downslope flow of water within the soil profile (throughflow) and sampling to identify soil properties related to the process of gully development. Throughflow was found to be controlled by the buried paleosol surface in this upper landscape position. The convergence of throughflow to the gully lower headwall was the predominant factor in lessening soil strength and in precipitating gully failure events. Although the exact mechanics of the failure events are not clear, failure planes follow cleavage planes within the soil mass caused by freezing-thawing and wetting-drying cycles. These cycles reduce soil stability by providing a greater number of cleavage planes. Failure debris is deposited against the gully wall, increasing gully stability. Overland flow was responsible for the removal of failure debris but not for bank erosion. Gully development at upper landscape positions such as this is very slow and probably depends on infrequent but intense rainfall events which carry the failure debris downstream and permit new failures. (Carroll-FRC)

EFFECT OF CATIONS ON COPPER ADSORPTION BY KAOLIN,
Maryland Univ. Eastern Shore, Princess Anne. Dept. of Natural Sciences.
G. C. Gupta, and F. L. Harrison.
Water, Air, and Soil Pollution, Vol 15, No 3, p 323-327, April, 1981. 2 Fig, 15 Ref.

Descriptors: *Copper, *Adsorption, Estuarine environment, Metals, Heavy metals, Calcium, Cations, Magnesium, Ions, Rivers, Kaolinite, Soil types, Desorption, Path of pollutants, Clay, *Kaolin.

The effect of cations on the adsorption of copper by kaolin was studied in pure systems. Kaolin powder was sieved to obtain the less than 62 micrometer fraction, treated with hydrogen peroxide to remove organic material, and equilibrated overnight with 0.5N HCl. After further treatment a dilute suspension of H-kaolin was added to clay to obtain a final concentration of 27 ppm in each of several test bottles. To each test bottle either calcium chloride or magnesium chloride was added to give a final concentration of 20, 40, 100, 200 mg/liter and distilled water to give a final volume of 10 ml. The samples were then spiked with high activity radioactive copper-64. After filtration the amounts of radioactivity on the filter and in the filtrate were measured separately, using a gamma ray well counter. Copper adsorption was plotted against calcium or magnesium concentrations. No appreciable change was noted in the distribution coefficient of adsorption in clay suspensions equilibrated with the chlorides in the concentration range of 90 to 200 mg/liter. These results support the findings of others that an increase in the concentration of calcium ions reduces the copper binding capacity of the bottom oozes in water bottles. This indicates that electrostatically bound heavy metals will enter the solution phases as calcuim ions and magnesium ions increase in the water, as may happen in a change from river to estuarine and marine systems. In dilute freshwater copper can compete with other divalent cations, but in seawater desorption of copper will occur because of the overabundance of other cations. (Baker-FRC)

SORPTION OF TRACE CADMIUM ON CLAY MINERALS AND RIVER SEDIMENTS: EFFECTS OF PH AND CD(II) CONCENTRATIONS IN A SYNTHETIC RIVER WATER MEDIUM,
State Univ. of New York at Binghamton. Dept. of Chemistry.
J. D. Reid, and B. McDuffie.
Water, Air, and Soil Pollution, Vol 15, No 3, p 375-386, April, 1981. 7 Fig, 33 Ref.

Descriptors: *Cadmium, *Sorption, Clays, Minerals, *Sediments, Fluvial sediments, Rivers, Acidity, Chemical properties, Hydrogen ion concentration.

Cadmium (II) sorption was studied at initial cadmium concentrations ranging from 1 to 1000 micrograms/liter with a constant solid phase concentration of 0.5 g/liter. The percentage sorbed at equilibrium increased sharply from pH 6.5 to 9.0, with a shift toward increased adsorption at lower initial concentrations, indicating specific, non-equivalent sites. Freundlich log-log plots were linear, with a slope of 0.83. Susquehanna River sediments (silt/clay fraction) showed similar behavior, sorbing cadmium somewhat more strongly than illite, as did montmorillonite, while kaolinite sorbed cadmium less strongly. Sorption on illite was not altered appreciably by removing the iron or manganese oxide coating with dithionite, by removing organic matter with hydrogen peroxide, or by using a carbonate-free medium. Equilibration time, desorption at lower pH, and the effect of citrate in shifting the sorption to higher pH were also studied. The data are presented in terms of cadmium speciation equilibria and possible sorption mechanisms. (Baker-FRC)

CHEMISTRY OF PRECIPITATION AT GAINESVILLE, FLORIDA,
Florida Univ., Gainesville. Dept. of Environmental Engineering Sciences.
C. D. Hendry, and P. L. Brezonik.
Environmental Science and Technology, Vol 14, No 7, p 843-849, July, 1980. 7 Fig, 2 Tab, 36 Ref.

Descriptors: *Precipitation, *Chemical analysis, *Acid rain, Acidic water, Sulfuric acid, Nitric acid, Nitrogen, Phosphorus, Nutrients, Eutrophication, Lakes, Plankton, Magnesium, Potassium, Sodium, Chlorides, Calcium, Rainwater analysis, *Florida.

Wet-only precipitation was collected manually from June 1976 to July 1977 on the University of Florida campus. Bulk precipitation was collected about 8 km northwest of Gainesville at a cypress swamp site located on a large pine plantation. Chemical analyses were performed on both types of samples. The rain was shown to be the predominant deposition mechanism for SO4(2-), NH4(+), NO3(-), Mg(2+), and K(+). Dry fallout is of comparable importance to rainfall for deposition of Na(+), Cl(-), and Ca(2+). Heavy metal levels were highly variable in both types of samples. The average concentrations of total nitrogen, NH4(+), and NO3(-) in bulk precipitation were 0.82, 0.12, and 0.23 mg nitrogen/liter, respectively. Averages for ortho and total phosphate were 24 and 85 micrograms phosphate/liter, respectively, in bulk precipitation and 19 and 34 micrograms/liter in wet-only samples. Highest nutrient concentrations occurred in spring and early summer. Total loadings of nitrogen and phosphate from bulk precipitation are above permissible rates, relative to eutrophication, for shallow lakes. The volume-weighted mean pH of wet-only precipitation was 4.53; bulk precipitation had a slightly higher pH. Lowest pH values occurred in spring and summer. Acidity titrations and ionic balances indicate that rainfall acidity resulted mainly from sulfuric acid (69%) and nitric acid (23%). (Baker-FRC)

LIBRARY OF THE URBANA-CHAMPAIGN

Descriptors: *Statistical analysis, *Rocks, *Chemical composition, *Seawater, Mathematical studies, Water analysis, Correlation analysis, Correlation coefficients.

The concept of a chemical steady state in the world ocean system is reevaluated on the basis of recent data on world average river composition and global mean composition of crustal rocks. The initial statistical analyses have been modified to reflect the new data. Improved correlations were found between mean oceanic residence times and water-rock partition coefficients. Also, improved correlations were found between water-rock partition coefficients and the electronegativity function. Such correlations give support to the idea that the average composition of seawater can be estimated using the electronegativities of the elements and the rate of input of dissolved components. Thus, a simple dynamic model is possible. Further, a detailed study of the scavenging of Th, Pb, Cu, Ni, and Cd in the marine environment suggests rapid rates of reaction which would favor the maintenance of a chemical steady state in the world oceans. BASIN LANDSCAPE-HALOGEOCHEMICAL METHOD OF EVALUATING THE NATURAL AND RECLAMATION CONDITIONS OF IRRIGATED TERRITORIES,
Akademiya Nauk SSSR, Moscow. Inst. of Soil Chemistry and Soil Science.
I. N. Stepanov, M. N. Brynskikh, O. S. Matveeva, N. I. Savitova, and E. I. Chembarisov.
Water Resources (English Translation), Vol 7, No 1, p 77-81, January/February, 1980. 3 Tab, 11 Ref. Translated from Vodnye Resursy, No 1, p 171-176, 1980.

Descriptors: *River basin development, *Chemical composition, Salts, Rivers, Mineralization, Minerals, Syr Darya Basin, Kura River Basin, Colorado River Basin, River water.

A new method for regional evaluation of the reclamation condition of irrigated territories is proposed. The method is based on using data from observations by the USSR Hydrometerological Service Administration on the hydrological and hydrochemical regime of river, irrigation and collector-drain waters. The method has the advantage that it uses long-term series of observations from 40 to 100 years, which are expanding with each additional year. The basin method is based on concepts concerning the effect of the soil cover on the chemical nature of river waters. The sequence of removal of ions from soils to river water and the change in their composition have a certain regularity which gives grounds to assume the opposite, that is, on the basis of the mineral content and chemical relationships of water from a flow draining a particular irrigated tract, its natural and reclamation condition can be judged. Use of the method to study the Syr Darya basin, the Kura basin and the Colorado River basin suggests that under various conditions, a relationship is noted between the water-management development of territories and the mineralization (chemical composition) of the waters of rivers draining them. HYDROCHEMISTRY OF A DOLOMITE KARST: THE BRUCE PENINSULA OF ONTARIO,
Department of the Environment, Burlington (Ontario). Lands Directorate.
D. W. Cowell, and D. C. Ford.
Canadian Journal of Earth Sciences, Vol 17, No 4, p 520-526, 1980. 5 Fig, 2 Tab, 20 Ref.

Descriptors: *Hydrology, *Karst, Dolomite, *Chemical composition, Calcium, Magnesium, Carbonates, Seasonal variations, Georgian Bay, Lake Huron, Lakes, Bays, Canada, Bruce Peninsula, Peninsulas, Chemical analysis, Water analysis, *Chemical properties, Hardness, Rivers, Wetlands, Surface waters.

The characteristics of waters of the Bruce Peninsula, a low-lying, karstified dolomite surface at latitude 45 N, were investigated. A total of 250 samples representing six hydrochemical environments were collected. These environments included: Georgian Bay and Lake Huron; inland lakes; rivers and streams; wetlands; conduit-flow springs; and diffuse-flow springs. The seasonal behavior and chemical separation of these waters are examined. Except for Georgian Bay and Lake Huron, the waters of the peninsula were very hard, ranging from 180-320 ppm Ca(2+) plus Mg(2+) (as CaCO3), and displayed increasing hardness as the summer season progressed. Surface recharge and conduit-flow springs were generally saturated with respect to calcite and dolomite. Only diffuse-flow springs, which are among the hardest of waters, are commonly undersaturated. These waters are also the easiest to distinguish chemically, and results of a linear discriminant function analysis suggest that other waters of the peninsula represent a single class. (Baker-FRC)

NITROGEN FIXATION AND METHANE METABOLISM IN A STREAM SEDIMENT-WATER SYSTEM AMENDED WITH LEAF MATERIAL,
Waterloo Univ. (Ontario). Dept. of Biology.
T-Y. Tam, C. I. Mayfield, and W. E. Inniss.
Canadian Journal of Microbiology, Vol 27, No 5, p 511-516, May, 1981. 4 Fig, 1 Tab, 25 Ref.

Descriptors: *Methane, *Nitrogen fixation, *Sediments, Streams, Leaves, Bacteria, Nitrification, Oxidation, Aerobic conditions, Anaerobic conditions, Ecosystems.

Although studies have been performed on the effect of allochthonous input of leaf materials on the energy budget in running water energy systems, there have been no previous studies of the effects of leaf material on the nitrogen cycle in streams. The present investigation focused on the reduction of acetylene and the production and oxidation of methane in a stream sediment-water system amended with either fresh leaves or autumn shed leaves incubated in the presence and absence of air. There was no net methane production in the sediment-water system except when leaf material was added. The addition of fresh leaves resulted in 2.2 times the methane accumulation found when autumn-shed leaves were added. Net methane production was not significantly affected by static incubation in the presence of air, with such production being about the same as anaerobic rates with fresh leaves or 79% of the anaerobic rates with autumn-shed leaves. The addition of leaf material readily supported acetylene reduction under aerobic conditions in the sediment-water system, while significantly less reduction of acetylene occurred under anaerobic gas phase incubation conditions. Fresh leaves were also more stimulatory of acetylene reduction than were autumn-shed leaves. (Carroll-FRC)

MEASUREMENTS OF HYDROGEN PEROXIDE IN RAINWATER,
Harvey Mudd Coll. Claremont, CA. Dept. of Chemistry.
G. L. Kok.
Atmospheric Environment, Vol 14, No 6, p 653-656, 1980. 2 Fig, 1 Tab, 10 Ref.

Descriptors: *Hydrogen peroxide, *Rain, *Oxidation, Chemical reactions, Precipitation, Claremont, California, *Rainwater.

Levels of hydrogen peroxide (H2O2), an important component of the polluted and clean troposhere, were measured in rainwater at Claremont, California, during rainfall events in 1978 and 1979. Concentrations were typically 1-160 ppb, but on three occasions levels in excess of 1 ppm were obtained: (1) September 5, 1978, a very intense evening shower, 1.59 ppm during the first three hours of rain, (2) July 17, 1979, an early morning shower, 1.14 ppm, and (3) January 31, 1979, during electrical storm activity, 1.09 ppm. H2O2 levels generally decreased with time during a storm. Measured values of H2O2 were lower than those predicted from the uptake of gas phase H2O2 into clouds. Possible mechanisms of loss are destruction during evaporation and reaction with SO2 or other acidic species. The predominant mechanism for uptake of H2O2 into rainwater is washout. (Cassar-FRC)

NEAP-SPRING TIDE SEQUENCES OF INTERTIDAL SHOAL DEPOSITS IN A MESOTIDAL ESTUARY,
Utrecht Rijksuniversiteit (Netherlands). Dept. of Sedimentology.
J. R. Boersma, and J. H. J. Terwindt.
Sedimentology, Vol 28, No 2, p 151-170, April, 1981. 13 Fig, 1 Tab, 20 Ref.

Descriptors: *Intertidal areas, *Tidal effects, *Sediment deposition, *Estuaries, Neap tides, Spring tides, Shoals, Sand waves, Dunes, Erosion, Westerschelde estuary, *Netherlands.

The hydrographic properties, the distribution and response pattern of various types of bedforms, and the sedimentary structures produced were observed in the mesotidal Westerschelde estuary, the Netherlands. Ebb and flood tides generally differed in strength; the resulting dominance changed over the neap-spring tide period. Parallel, long-crested sand waves and irregular short-crested dunes responded differently to the neap-spring variation in current velocity. The internal structure largely consisted of unidirectional cross-bedding, separated into a succession of tidal bundles, each formed during one tide. These tidal bundles were arranged in a lateral sequence reflecting neap-spring tide periods and differed in character with location. Within the tidal bundle, reactivation, full vortex and slackening structures reflected acceleration, full stage, and deceleration of flow, respectively, in the dominant tide, usually the flood tide. The full vortex structures tended to be well developed around spring tide and disappear towards neap tide. The subordinate tide carved pause planes which enclose the tidal bundles. These pause planes can be either erosional or depositional. (Cassar-FRC)

GEOCHEMISTRY OF A SUBARCTIC SALT MARSH ENVIRONMENT,
National Water Research Inst., Burlington (Ontario). Process Research Div.
W. A. Glooschenko, and J. A. Capobianco.
Marine Geology, Vol 37, No 3/4, p 231-240, September, 1980. 1 Fig, 3 Tab, 31 Ref.

Descriptors: *Salt marshes, *Chemical composition, Trace elements, Marshes, Geochemistry, Tidal marshes, Magnesium, Calcium, Potassium, Iron, Manganese, Silicon, Aluminum, Phosphorus, Sulfur, Titanium, Copper, Lead, Nickel, Cobalt, Cadmium, Chromium, Mercury, Zinc, North Point, *Ontario.

Samples were taken from a coastal salt marsh located at North Point, Ontario, on the southwestern shore of James Bay. The climate of the area is subarctic, with a dominant upland vegetation of northern boreal forest and large inland areas of bog and fen peatlands. The area is underlain by Paleozoic rocks of Ordovician, Silurian, and Devonian age. Extensive silty tidal flats are present, which are reworked by ice scouring during periods of thaw. The elements Ti, Mg, Ca, K, Na, Fe, Mn, Si, Al, P, and S were determined in the samples by x-ray fluorescence. Trace elements Cu, Pb, Ni, Co, Cd, Cr, and Zn were determined by digesting 2.5 g of sediment with a mixture of HCl/HNO3 and using atomic absorption spectrophotometry. The studies indicated that the parent material from which the sediments were derived, i.e., is Paleozo-

ic carbonates rather than Canadian Shield igneous and metamorphic rocks, is the major controlling factor determining elemental composition of these materials. Other factors such as acidic or basic nature of aluminosilicates, hydrated iron oxides, clay and sand content, sulfides, and organic matter influence sediment composition within the salt marsh in terms of total elemental compositon. However, since the marsh sediments and soil represent a system changing through time, with exposure to saline and fresh water, and thus varying redox potential, it would be expected that sediments would change in terms of soluble and exchangeable cations and anions. PERPETUAL SHOALS AT THE ENTRANCE TO CHESAPEAKE BAY: FLOW-SUBSTRATE INTERACTIONS AND MUTUALLY EVASIVE NET CURRENTS,
Waterways Experimental Station, Stevenville, MD.
M. A. Granat, and J. C. Ludwick.
Marine Geology, Vol 36, No 3/4, p 307-323, July, 1980. 5 Fig, 1 Tab, 27 Ref.

Descriptors: *Water currents, *Bays, Bights, Sounds, Estuaries, *Chesapeake Bay, *Substrates, Shoals, Sandbars, Mud flats, Sediment, Tidal currents, Wave action.

Shoals in coastal plain estuaries are sites of greater-than-average net sediment accumulation which exist in a state of quasi-equilibrium with tidal currents and wave action. Studies of the Inner Middle Ground Nine Foot Shoal, a compound parabolic shoal in the entrance to the Chesapeake Bay, indicate that it is in dynamic interaction with mutually evasive ebb and flood tidal currents. This interaction is perpetuated through a close relationship between flow and substrate. A modest change in one attribute as a result of natural or man-induced variation causes a change in the other in an attempt to maintain a pseudo-balanced system. Comparisons among six bathymetric surveys taken during the past 127 years trace development of the shoal from two linear sediment bodies to its present double parabolic morphology. The existing particle size distributions of the surface sediments are systematically related to the present morphology and seem to be in adjustment with the ambient currents. Tidal currents of the area were sufficient in velocity to easily erode the surface sediments of the shoal. Various flow asymmetries or inequalities were examined from eight current meter stations to determine the dominant directions and to summarize the hydraulic regime. Different flow dominance was indicated depending on the attribute considered. Bathymetric influence on the flow direction of near-bottom currents is illustrated by diverted currents and shielding. Sediment circulation cell was a manifestation of the mutual evasion of ebb and flood tidal currents. Feedback exists between flow and substrate and results in a system in quasi-equilibrium. GEOMORPHIC AND HYDRAULIC EVOLUTION OF TIDAL CREEKS ON A SUBSIDING BEACH RIDGE PLAIN, NORTH INLET, S.C.,
South Carolina Univ., Columbia. Dept. of Geology.
L. R. Gardner, and M. Bohn.
Marine Geology, Vol 34, No 3/4, p M91-M97, February, 1980. 3 Fig, 14 Ref.

Descriptors: *Tidal marshes, *Evolution, Beaches, Erosion, Shores, *Submergence, Drowning, Submerged lands, Tide lands, North Inlet, South Carolina.

Stratigraphic and geomorphic features of a small marsh basin near Noth Inlet, South Carolina, are described. The basin is in an early stage of evolution under conditions of slow submergence. These features suggest that the tidal creek draining this basin was originally a small fresh-water stream which has gradually adjusted its hydraulic geometry to an increasing volume of tidal flow imposed by submergence. A generalized model of the evolution ofhydraulic geometry in response to submergence is presented as a complement to the Mudge-Davis model of marsh evolution. The dominant sediment of the interridge area of marsh was shown to be sand. Mud and silt were confined to a relatively narrow zone along the main tidal channel. That the area was originally a coastal forest much like that landward of the present marsh is evidenced by the presence of stumps and roots in the sandy sediment of the marsh along with occasional relic cat eye ponds on the surface of the sandy marsh. In the early stages of its adjustment to tidal influence the stream apparently eroded a considerable volume of sand, which subsequently was partly replaced by mud. Eventually the entire watershed of the original stream will be subject to tidal inundation, and further growth in the volume of tidal flow will subside. The stream will then achieve a condition of mature stability, in which the meanders have little tendency to migrate. (Baker-FRC)

ENRICHMENT AND ASSOCIATION OF BACTERIA AND PARTICULATES IN SALT MARSH SURFACE WATER,
Stanford Univ., CA. Dept. of Civil Engineering.
R. W. Harvey, and L. Y. Young.
Applied and Environmental Microbiology, Vol 39, No 4, p 894-899, April, 1980. 3 Fig, 1 Tab, 31 Ref.

Descriptors: *Bacteria, *Salt marshes, *Particulate matter, Tidal effects, Population dynamics, Tidal marshes, Surface water, Sippewissett salt marsh, Massachusetts, Palo Alto salt marsh, California.

The relationship between particulate material and populations of surface layer bacteria was investigated in a salt marsh. At two sampling sites, Sippewissett salt marsh in Falmouth, Massachusetts, and Palo Alto salt marsh in Palo Alto, California, elevated counts of bacteria were found during outgoing tides in surface microlayers. The degrees by which bacteria were concentrated into the surface microlayer were linearly dependent upon surface concentration of particulate matter. Bacterial populations in the subsurface water were largely planktonic, but a significant percentage of the bacteria in the microlayer were attached to particulate material. Both bacterial populations were grown on seawater nutrient agar, and the microlayer bacteria grew more successfully than did the bacteria from subsurface waters. Successful growth was positively correlated with the fraction of bacteria attached to particulate matter. It seems that the particulates in the microlayer waters of the salt marsh influenced the observed increase in both the readily grown and the total numbers of bacteria. (Small-FRC)

POPULATIONS OF METHANE-PRODUCING BACTERIA AND IN VITRO METHANOGENESIS IN SALT MARSH AND ESTUARINE SEDIMENTS,
Clemson Univ., SC. Dept. of Microbiology.
W. J. Jones, and M. J. B. Paynter.
Applied and Environmental Microbiology, Vol 39, No 4, p 864-871, April, 1980. 6 Tab, 29 Ref.

Descriptors: *Methane bacteria, *Marine sediments, *Salt marshes, Methane, Estuaries, Spartina, Sediments, Sapelo Island, Georgia.

The methanogenic populations of various marine sediments, particularly salt marsh sediments, were quantified, and the in vitro rates of sediment methanogenesis were measured. Most probable numbers of methanogens were determined using an anaerobic, habitat-simulating culture medium with 80% H2 plus 20% CO2 as substrate. Methane producing organisms were found at all depths tested (0 to 36 cm) in salt water and salt marsh sediments. For the short Spartina marsh sediments of Sapelo Island, Georgia, populations were maximal at the 5 to 7 cm depth, while in the tall Spartina marsh, populations were maximal in the upper 0 to 2 cm zone. In vitro rates of methanogenesis with short Spartina sediments incubated under 80% H2-20% CO2 indicated that the 5 to 7 cm region exhibited maximal activity. When incubated under 100% N2 rates of methanogenesis were similar to rates with 80% H2-20% CO2. Replacing the N2 with H2 resulted in an eight-fold decrease in the rate of methanogenesis. (Small-FRC)

SPECIFIC INHIBITION OF NITRITE OXIDATION BY CHLORATE AND ITS USE IN ASSESSING NITRIFICATION IN SOILS AND SEDIMENTS,
Cawthron Inst., Nelson (New Zealand).
L. W. Belser, and E. L. Mays.
Applied and Environmental Microbiology, Vol 39, No 3, p 505-510, March, 1980. 5 Fig, 4 Tab, 11 Ref.

Descriptors: *Nitrification, *Intertidal areas, Sediments, Soils, Nitrates, Oxidation, Ammonium, Chlorates, Natural waters, New Zealand.

The selectivity of chlorate inhibition on the oxidation of nitrite, with respect to possible inhibition of ammonium oxidation, was investigated. The purpose was to develop a method for measuring ammonium oxidizer activity in which only nitrite need be measured. Initial work was carried out with intertidal sediments collected at the Delaware Inlet, Nelson, New Zealand. Two pasture soils were also used, one a Wakapuaka sandy loam and the other a Ronga silty loam. Both soils were in permanent clover grass pastures grazed by either sheep or cattle. The application of chlorate to the samples prevented nitrite from being oxidized to nitrate. The effectiveness and specificity of chlorate were then tested with pure cultures of nitrite and ammonium oxidizers, as well as in soil and sediment slurries. It was concluded that chlorate had relatively little inhibitory effect on ammonium oxidation. However, under some conditions chlorate was not completely effective in blocking nitrite oxidation, and the causes of this were investigated. The technique was designed to check for incomplete blockage. The technique as developed had two advantages over methods where both nitrite and nitrate are measured. First, when automated methods are not available, nitrite is much simpler to measure and requires a smaller sample size. Second, in soils with high nitrate background, this method will be much more sensitive, as nitrite will normally be undetectable at the beginning of the incubation. (Baker-FRC)

EFFECT OF ESTUARINE SEDIMENT PH AND OXIDATION-REDUCTION POTENTIAL ON MICROBIAL HYDROCARBON DEGRADATION,
Louisiana State Univ., Baton Rouge. Lab. for Wetland Soils and Sediments.
G. A. Hambrick, III, R. D. DeLaune, and W. H. Patrick, Jr.
Applied and Environmental Microbiology, Vol 40, No 2, p 365-369, August, 1980. 5 Fig, 19 Ref.

Descriptors: *Sediments, *Hydrocarbons, Mineralization, *Estuarine environment, Estuaries, Coasts, Acidity, Oxidation, *Microbial degradation, Microorganisms, Degradation, Bottom sediments.

The objective of this study was to determine and compare the relative rates of mineralization in estuarine sediment of two C-14 labeled petroleum hydrocarbons, octadecane and naphthalene, as affected by different pH levels and redox potentials. Three sets of sediment-water suspensions were used, incubated at one of three pH levels, 5.0, 6.5, or 8.0. Hydrocarbon mineralization rates were in-

UNIV. OF ILL. URBANA-CHAMPAIGN

ferred from the activity of respired carbon dioxide. Sediment pH and oxidation-reduction potential were important factors governing the population of hydrocarbon-degrading microorganisms in the sediment and subsequent mineralization rates. Highest mineralization rates occurred at pH 8.0, and the lowest occurred at pH 5.0. At all pH levels mineralization decreased with decreasing oxidation-reduction potential, that is, increasing sediment anaerobiosis. In general, mineralization rates for octadecane were greater than those for naphthalene. Aerobic microorganisms in the oxidized sediment were more capable of degrading hydrocarbons than anaerobic microorganisms in reduced sediment of the same pH. (Baker-FRC)

ENUMERATION AND RELATIVE IMPORTANCE OF ACETYLENE-REDUCING (NITROGEN-FIXING) BACTERIA IN A DELAWARE SALT MARSH,
Delaware Univ., Newark. Coll. of Marine Studies.
H. J. Dicker, and D. W. Smith.
Applied and Environmental Microbiology, Vol 39, No 5, p 1019-1025, May, 1980. 2 Fig, 2 Tab, 42 Ref.

Descriptors: *Bacteria, *Salt marshes, Marshes, Bacterial analysis, Nitrification, Tidal marshes, Nitrogen, Seasonal variations, Temperature effects, Clostridium, Azotobacter, Desulfovibrio, *Delaware, *Nitrogen fixation.

Four sites were selected for study in the Canary Creek marsh adjacent to the University of Delaware Marine Station facilities in Lewes, Delaware. The stations were located in four different vegetational areas of the marsh. Three groups of N2-fixing bacteria were enumerated from the top centimeter of the surface in the four areas. The results over a period of sampling for nine months showed that there were no discernible seasonal patterns for any of the groups enumerated (Azotobacter sp., Clostridium sp., and Desulfovibrio sp). Azotobacter sp. were present in numbers of 10 to the seventh power per g of dry mud, whereas the two anaerobic fixers were present in much lower numbers, 10 to the third power to 10 to the fourth power per gram of dried mud. There were no differences in the numbers of each group among the different vegetational areas, thus indicating that there was a heterogeneous population of N2 fixers present. Additional studies indicate that the activity of sulfate reducers (Desulfovibrio sp.) may account for as much as 50% of the total observed acetylene reduction activity. Oxygen was found to exert little effect on the observed acetylene reduction activity, indicating that stable aerobic and anaerobic microenvironments exist in the surface layer of marsh sediments. DOES SALT MARSH FERTILIZATION ENHANCE SHELLFISH PRODUCTION. AN APPLICATION OF FLOW ANALYSIS,
Massachusetts Univ., Amherst. Dept. of Forestry and Wildlife Management.
J. T. Finn, and T. M. Leschine.
Environmental Management, Vol 4, No 3, p 193-203, May, 1980. 3 Fig, 2 Tab, 27 Ref.

Descriptors: *Fertilizers, *Shellfish, *Flow, *Nitrogen compounds, Nutrients, Marshes, Wetlands, Salt marshes, Ecosystems, Barataria Bay, Louisiana, Sippewissett Marsh, Massachusetts, Model studies, Wastewater disposal, Spartina, Aquatic plants.

Flow analysis was used to determine that adding nitrogen fertilizer to Spartina salt marsh sediment was not an efficient way to enhance shellfish growth. Nitrogen flow models for Barataria Bay salt marsh, Louisiana, and Sippewissett Marsh, Cape Cod, indicated that in both locations only 3% of added N reached the shellfish, despite the great physical differences and despite the inclusion of considerably more microbial processing of N in the Barataria Bay model. The most efficient N transfer would have to bypass Spartina growth, decomposition, and detrital feeding. (Cassar-FRC)

THERMOSTABILIZATION OF ENTEROVIRUSES BY ESTUARINE SEDIMENT,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
P-F. Liew, and C. P. Gerba.
Applied and Environmental Microbiology, Vol 40, No 2, p 305-308, August, 1980. 5 Fig, 17 Ref.

Descriptors: *Sediments, *Enteroviruses, *Estuarine environment, Temperature effects, Adsorption.

The protection of viral infectivity via adsorption to particulates was investigated. Particular attention was given to the possibility of an increased resistance to thermoinactivation resulting from the contact of the viruses with sediments. Dried estuarine sediment and artificial seawater were used in the study. The effect of sediment on enterovirus survival was assessed by comparing inactivation of a virus inoculum added to 40 ml of seawater in a 100-ml flint-glass bottle with inactivation of a similar virus inoculum in an identical volume of seawater containing sediment. The final concentration of virus in each bottle was 25,000 plaque-forming units per ml. Poliovirus survival was prolonged at 24 and 37C, but not at 4C in the presence of sediment over the time periods observed. Further inactivation studies were performed at 50 and 55C to maximize the thermal effects, and similar protection was noted. The supernatant fluid from a mixture of seawater and sediment lacked a protective effect against thermoinactivation, suggesting that prolonged virus survival in the presence of sediment was due to adsorption to particulates. From these observations it appears that the adsorption of enteroviruses to estuarine sediments may play a significant role in protecting them against thermoinactivation. (Baker-FRC)

THE ABUNDANCE OF ESTUARINE LARVAL AND JUVENILE FISH IN A SOUTH CAROLINA INTERTIDAL CREEK,
South Carolina Univ., Columbia. Belle W. Baruch Inst. for Marine Biology and Coastal Research.
E. L. Bozeman, Jr., and J. M. Dean.
Estuaries, Vol 3, No 2, p 89-97, June, 1980. 5 Fig, 3 Tab, 26 Ref.

Descriptors: *Estuaries, *Fish populations, *Larvae, *Juvenile fish, *North Inlet Estuary, *South Carolina, Intertidal areas, Tides, Saline water fish, Marine fish, Aquatic environment, Aquatic animals, Wildlife, Immature growth stage, Eel, Atlantic menhaden, Creeks.

The population of larval and juvenile fish was measured in a small intertidal creek in the North Inlet Estuary, South Carolina, during October 1974 to May 1975. Five species accounted for 99.3% of the 573,739 individual fish captured: spot, Leiostomus xanthurus; pinfish, Lagodon rhomboides; Atlantic menhaden, Brevoortia tyrannus; Atlantic croaker, Micropogon undulatus; and speckled worm eel, Myrophis punctatus. A total of 16 species were represented. The collection method, blocking the channel at high tide and catching the fish in a quantitative sampling net as they left on the ebb tide, was reliable. Larvae were most abundant in February and March and moved to the open sea in the spring. (Cassar-FRC)

THE SIGNIFICANCE OF THE SUBMARINE GEOLOGY OF UPPER SPENCER GULF, SOUTH AUSTRALIA, TO ENVIRONMENTAL DECISION-MAKING,
Adelaide Univ. (Australia). Dept. of Geology.
J. R. Hails, V. A. Gostin, and G. E. Sargent.
Search, Vol 11, No 4, p 115-116, April, 1980. 2 Fig.

Descriptors: *Environmental effects, *Shore protection, Water pollution effects, Sediment transport, Aquatic plants, Ecological effects, Sea grasses, Mangrove swamps, Clays, Metals, Fate of pollutants, *Spencer Gulf, *Australia, Estuaries.

Study of more than 300 undisturbed vibrocores and box cores from the upper Spencer Gulf, South Australia, indicated that environmental damage could result from proposed industrial development in the coastal areas. Any damage to the extensive seagrass meadows or mangrove plants by pollutants or physical removal could interrupt shoreline equilibrium, releasing shell grit and sand to fill channels. Pollutants discharged into the water would be likely to remain in the nearshore environment because of poor water circulation and adsorption by the underlying stiff clays. (Cassar-FRC)

EFFECT OF SOLAR RADIATION AND PREDACIOUS MICROORGANISMS ON SURVIVAL OF FECAL AND OTHER BACTERIA,
Tasmania Univ., Hobart (Australia). Dept. of Agricultural Science.
J. McCambridge, and T. A. McMeekin.
Applied and Environmental Microbiology, Vol 41, No 5, p 1083-1087, May, 1981. 1 Fig, 3 Tab, 14 Ref.

Descriptors: *Sewage bacteria, *Estuarine environment, *Solar radiation, Seawater, Bacteria, Escherichia coli, Coliforms, Predation, Pathogens.

Although the effect of solar radiation on the survival of sewage bacteria in seawater has received considerable attention, little attention has been paid to pathogens and fecal matter other than coliforms or to the interaction between naturally occurring microbial predators and solar radiation. This study compared the survival of a range of bacteria associated with feces when exposed to solar radiation and examined the interrelationship between microbial predators and solar radiation in estuarine water samples. Significantly greater declines in the numbers of Escherichia coli cells were observed in estuarine samples exposed to both naturally occurring microbial predators and solar radiation than in samples exposed to only one of these factors. The effect of solar radiation on microbial predators was found to be negligible. However, sewage bacteria were susceptible to ligh-induced decay in varying decrees. Klebsiella pneumoniae had the lowest survival rate in estuarine water samples both in the dark and when exposed to solar radiation. The survival rates of the other sewage bacteria were next lowest for E. coli, followed in order of increasing survival levels by Salmonella typhimurium, Streptococcus faecium, Enterobacter aerogenes, and Erwinia herbicola. These results demonstrate that naturally occurring microbial predators and solar radiation interact to produce part of the observed decline of sewage bacteria in estuarine water samples and that different bacteria are affected by solar radiation to different degrees. COASTAL BERMUDAGRASS YIELD AND SOIL PROPERTIES AS AFFECTED BY SURFACE-APPLIED DAIRY MANURE AND ITS RESIDUE,
Alabama Agriculture Experimental Station, Auburn.
Z. F. Lund, and B. D. Doss.
Journal of Environmental Quality, Vol 9, No 1, p 157-262, January-March, 1980. 9 Fig, 1 Tab, 6 Ref.

Descriptors: *Land disposal, *Manure, *Grasses, Crop yield, Farm wastes, *Fertilizers, *Bermudagrass, Dairy industry, Nitrogen, Acidity, Water pollution sources.

An experiment was performed to yield information on how manure affects soil properties and how long plants respond to residue from surface-applied manure. Dairy manure was applied for three years as a solid at rates of 45 and 90 metric tons/ha/yr and as a liquid at rates of 45, 90, and 135 metric tons/ha/yr on plots of Ditham loamy sand and Lucedale fine sandy loam. Mineral fertilizers were used on control plots. At the beginning of the residual phase of the study, residue from the manure three years after the final application was still producing considerably higher yields of coastal bermudagrass on both soils compared to the check plots. By the end of three cropping seasons, nitrogen was one of the most important limiting factors of production on both soils. Manure application increased levels of K and Mg and the pH of the subsoils. There was some downward movement of P. Thus, manure can be used to correct subsoil acidity in coarse-textured soils. However, the landspreading of manure may cause problems by polluting runoff and groundwater. (Small-FRC)

Descriptors: *Irrigation water, *Irrigation-return flow, *Tailwater, Water quality, Water supply, Water reuse, Dissolved solids, Suspended sediments, Pesticide residues, Agricultural chemicals, Water conservation, Cost analysis, *Impaired water use, *Central Valley, California.

Irrigation tailwater and other components of irrigation return flows were investigated in two representative sites in the Central Valley of California. Management of tailwater depends on the quantity and the quality of the water. When water is scarce tailwater is not discharged, or is used close to the site of production. Beneficial uses of tailwater include irrigation of crops and pasture, maintenance of wetland/waterfowl habitats, livestock water supply, groundwater recharge, maintenance of low flows in stream beds, repulsion of salinity in tidal estuaries, fish migration and spawning, warm water fish habitat, navigation, recreation and aesthetics, and municipal/industrial water supply. The use will depend on the quality of the water as well as the quantity. Poor quality of tailwater is caused by the presence of dissolved mineral salts, sediments, and agricultural chemicals. There is no single, universally-applicable control technology for irrigation tailwater, but low cost methods involve reducing the production of tailwater. This may be done by changing methods, use of variable interest and cost rates, and differential water costs. (Brambley-SRC)

THE HARVEST OF MICROALGAE FROM THE EFFLUENT OF A SEWAGE FED HIGH RATE STABILIZATION POND BY TILAPIA NILOTICA. PART 2: STUDIES OF THE FISH PONDS,
Asian Inst. of Tech., Bangkok (Thailand). Div. of Agricultural and Food Engineering.
P. Edwards, O-A. Sinchumpasak, and M. Tabucanon.
Aquaculture, Vol 23, No 1-4, p 107-147, April, 1981. 6 Fig, 6 Tab, 25 Ref.

Descriptors: *Fish ponds, *Wastewater treatment, *Growth, Stabilization ponds, Algae, Phytoplankton, Effluent, Economic aspects, Tilapia, Fish stocking, Biomass, *Impaired water use.

Utilization of sewage-grown phytoplankton as in situ food for algae-feeding fish provides a potentially economic means of harvesting this protein source. The growth of Tilapia nilotica as a function of the concentration of phytoplankton in the water was investigated to acquire information needed for the design of fish culture systems involving the recycling of organic wastes. Phytoplankton concentration was varied by changing the flow rates and therefore the detention times of the fish ponds receiving wastes from a high rate stabilization pond. Tilapia nilotica grew well in the 4-cum concrete fish ponds, but ceased to grow after 3 months, regardless of stocking density or mean pond algal concentration. A fish stocking density of 10 per cubic meter may produce a high yield of small individual fish suitable for animal feed. Yields obtainable using a 4-cubic meter concrete pond system based on 3 month growing seasons may be similar to those for larger earth ponds with a single fish crop each year. A linear relationship exists between fish yields and mean phytoplankton concentration in the fish ponds. Good fish growth may be achieved with algal concentrations of 70 milligrams per liter. The dominance of phytoplankton in fish guts and the high crude food conversion ratios, based on phytoplankton added and retained in the fish ponds, demonstrated the high nutritional value of waste grown microalgae. Reductions of detention time, and therefore of mean pond phytoplankton concentrations, resulted in increases in the efficiency of fish production per unit phytoplankton biomass. Since fish growth was directly correlated with mean pond phytoplankton concentration, maximum efficiency would require large areas of land to obtain significant fish yields. (Carroll-FRC)

THE HARVEST OF MICROALGAE FROM THE EFFLUENT OF A SEWAGE FED HIGH RATE STABILIZATION POND BY TILAPIA NILOTICA. PART 3: MAIZE CULTIVATION EXPERIMENT, BACTERIOLOGICAL STUDIES, AND ECONOMIC ASSESSMENT,
Asian Inst. of Tech., Bangkok (Thailand). Div. of Agricultural and Food Engineering.
P. Edwards, O-A. Sinchumpasak, V. K. Labhsetwar, and M. Tabucanon.
Aquaculture, Vol 23, No 1-4, p 149-170, April, 1981. 3 Fig, 5 Tab, 17 Ref.

Descriptors: *Land application, *Fish ponds, *Wastewater treatment, Effluents, Nitrogen, Crop yield, Irrigation, Coliforms, Algae, Phytoplankton, Economic aspects, Stabilization ponds, *Impaired water use.

The fertilization potential of effluent from a fish pond, which in turn received effluent from a sewage-fed high rate stabilization pond, for maize cultivation was investigated. Plots received composite fish pond effluent, raw sewage, or tap water and one of three levels of commercial nitrogen fertilizer. A linear relationship was found between maize yield and total nitrogen applied, regardless of the nitrogen source. However, differences in soil fertility prevented the development of an absolute relationship between maize yield and total nitrogen applied. Effluent from the fish ponds contained higher concentrations of fecal coliforms than are permitted under the World Health Organization standard for wastewater reuse for crops eaten cooked and for fish culture. Significant amounts of algae passed through the fish ponds when the phytoplankton concentration was high enough to produce good fish growth. As a result, a large land area was required for the maize crops irrigated with effluent from the ponds. About 63 hectares would be needed to treat and recycle domestic wastewater from a city of 100,000 people. The land area ratios were 1.86:1:10.25 for the high rate stabilization pond, the fish pond, and the maize plot, respectively. The study results suggest that there is little advantage in incorporation of a high rate pond in a fish-maize system, since fish do not harvest the phytoplankton as efficiently as they are produced in the high rate stabilization pond and since fecal coliform counts are high in the fish pond effluent. Use of a stabilization pond system composed entirely of earth ponds modified for fish and crop cultivation as well as for waste treatment probably would provide a more effective means of recycling sewage into fish. If a high rate stabilization pond is to be used, direct harvesting of the phytoplankton from the effluent for use as animal feed is probably the most practical means to exploit the system. (Carroll-FRC)

SODIUM-POTASSIUM RATIOS IN SOIL SOLUTION AND PLANT RESPONSE UNDER SALINE CONDITIONS,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
D. Devitt, W. M. Jarrell, and K. L. Stevens.
Soil Science Society of America Journal, Vol 45, No 1, p 80-86, 1981. 3 Fig, 3 Tab, 23 Ref.

Descriptors: *Wastewater disposal, *Salinity, *Crop production, *Potassium, *Sodium, Land disposal, Soil solution, Effluents, Irrigation, Electric powerplants, Electrical conductivity, Nutrients, Soil-water-plant relationships, Chemical composition.

The use of cooling tower water from electrical generating plants to irrigate agricultural crops is being investigated. These effluents are quite saline and are usually high in sodium and comparatively low in potassium, resulting in a low potassium to sodium ratio. This study investigated the soil and plant factors that might affect the uptake and distribution of potassium by wheat plants irrigated with high-sodium, low-potassium water synthesized to represent cooling tower water. Lysimeters filled with either Holtville clay loam or San Emigdio sandy loam planted with wheat were irrigated with three concentrations of simulated cooling tower waters at electrical conductivities of 2.1, 4.2, or 7.1 mmho per centimeter. The concentrations of both sodium and potassium in the saturation extracts increased and the accumulation of sodium in leaves of the wheat plants greatly increased when the salinity of the irrigation water was increased. A significant inverse relationship was found between the potassium in plant leaves and the depth-weighted potassium in solution, as well as between sodium in leaves and potassium in leaves at harvest. The product of potassium/sodium in soil solution and the root length density, summated over

UNIV. OF ILL. URBANA-CHAMPAIGN

each depth increment sampled, was found to be the best indicator of the potassium to sodium ratio found in leaves at harvest. The ratio of potassium to sodium concentrations found in the soil solution appears to be a better indicator of potassium uptake by wheat than is the absolute concentration of potassium measured in the solution. BEFORE THE WELL RUNS DRY: A HANDBOOK FOR DESIGNING A LOCAL WATER CONSERVATION PLAN.
New England River Basins Commission, Boston, MA.
Available from the USGS, Dist. Br. Text Prod. Sect. 604 S. Pickett St. Alexandria, VA. 22304, Price: $4.50. Geological Survey Resources and Land Investigations Program Report, October 1980. 95 p, 30 Fig.

Descriptors: *Water conservation, *Water management, *Planning, *Water supply, Water use, Municipal water, Domestic water, Water loss, Drought, Water shortage, Water demand, Water costs, Potential water supply, Public utility districts, *New England River Basins Commission.

A seven-step procedure for designing a water conservation plan is described in textbook fashion. This procedure forces the water supplier to consider the full range of options available and the potential impacts of each option on the utility, the users, and the community. The handbook presents five supply management programs to consider which will reduce water loss and waste within the supply system. In addition to the supply management programs, three demand management programs, pricing, education, regulation and their impacts are discussed. (USGS)

WATER CONSERVATION DEVICES FOR NEW OR EXISTING DWELLINGS,
Pennsylvania State Univ., University Park. Inst. for Research on Land and Water Resources.
W. E. Sharpe.
Journal of the American Water Works Association, Vol 73, No 3, p 144-149, March, 1981. 4 Tab, 10 Ref. OWRT-A-999-PA(7), 14-34-0001-1140.

Descriptors: *Performance evaluation, *Water conservation, *Plumbing, Urban areas, Retarded flow, Flow regulators, Flow velocity, Domestic water.

The performance of water conservation devices and fixtures developed for home use is discussed. Many devices have been developed to reduce the amount of water used to flush a toilet, including dams, partitions, and various inserts to displace water in toilet tanks. Damming, displacement, and flush mechanism modification devices are compared on the basis of water use reduction efficiency, cost installation problems, and performance under conditions of actual use. Maximum water reduction efficiencies occurred with two-cycle flush mechanism devices. Other flush modifications rated second, and toilet dams rated third. These results do not indicate solids clearance from the toilet bowl or deal with other potential problems. Plastic bottles were the easiest device to install and also cost the least. Toilet dams were the next cheapest, followed by flush modification mechanisms. Little information is available on performance. One study found that 100% of bottles installed were still in place two years later, while only 42, 50, and 92% of other toilet devices were still in place. There have also been problems with water saving toilets, specifically inadequate flushing of solid material in some installations. Shower devices and water faucet devices have performed satisfactorily. (Small-FRC)

3E. Conservation In Industry

GERBER SAVES 465,000 GALLONS OF WATER/DAY,
R. Banner.
Food Engineering, Vol 52, No 3, p 105-107, March, 1980. 1 Fig.

Descriptors: *Water reuse, *Food processing industry, Industrial wastes, Water demand, Drought, Economic aspects, Reclaimed water, Water renovation, Cooling water, Economic aspects.

Gerber was able to reduce its water usage in Oakland, California from 500,000 gallons per day to 35,000 per day, just by recycling cooling water used in its hot-fill and retort cooking process. A further refinement planned for the system will enable Gerber to save as much as $40,000 per year in steam-generating costs, by recycling hot water as well as cool water. Gerber originally had considered water conservation 16 years ago, when the plant was remodeled, and had the necessary equipment installed at that time. However, it was the cost of utilities and energy, triggered by the California drought of 1977, that made the system attractive enough to use. In this system, Gerber is reusing the cooling water that has passed through the retorts and sterilizer/cooler. This is accomplished by cooling and filtering the water for reuse rather than flushing the cookers with a fresh supply of city water for each cook cycle. When the whole system begins to operate, about 314,000 gallons of water will be saved per day. (Baker-FRC)

WATER AND WASTEWATER RECLAMATION: AN ECONOMICAL ANSWER TO INDUSTRIAL WASTES AND POLLUTION,
Culligan Inc., Northbrook, IL.
J. Mulvihill.
Industrial Wastes, Vol 26, No 4, p 14-16, July/August, 1980. 1 Fig.

Descriptors: *Industrial wastes, *Reclaimed water, Water, Water reuse, Wastewater renovation, Water use, Wash water, Impaired water use.

Several examples are cited of water being reused or made to serve several purposes before being discharged to the sewer system. One example, in operation at many places in the United States, involves the washing of trucks, buses and trains, where the wash water is recycled for reuse. Another example is found in a motel, where the shower and sink water from the motel rooms is chlorinated, passed through a multi-media depth filter, then through a carbon filter, rechlorinated, and used for on-premise laundry. The laundry wastewater is collected and goes through the same type of system as the motel gray water. Water from the laundry gray water system is colored and scented and used for toilet flushing. A third type of process using reclaimed water is a coal processing plant reusing its coal washing wastewater. The reclamation process involves chemical clarification followed by alternating multi-media filters. Additional examples include a rolling steel mill, a cannery, and a metal conduit manufacturer. Designing such a system requires thorough knowledge of the incoming water's chemical and biological make-up, the breakdown of chemical components being used in the process and their effects, the chemical and physical elements added to the water during its intended use, and the available treatment methods, both chemical and physical in nature. (Baker-FRC)

3F. Conservation In Agriculture

PERFORMANCE OF BEARING CHERRY AND PRUNE TREES UNDER VERY LOW IRRIGATION RATES,
S & E Irrigated Agriculture Research and Extension Center, Prosser, WA.
E. L. Proebsting, Jr., J. E. Middleton, and M. O. Mahan.
Journal of the American Society for Horticultural Science, Vol 106, No 2, p 243-246, March, 1981. 4 Tab, 9 Ref.

Descriptors: *Irrigation requirements, *Fruit crops, Cherries, Prunes, Trees, Trickle irrigation, Soil moisture, Wilting point, Plant growth, Washington, Water shortage, Soil water, Water requirements, Agriculture, Water conservation, Orchards, Water stress.

The minimum amount of irrigation water needed to keep cherry (Prunus avium L.) and prune (Prunus domestica L.) trees alive during a 1 year water shortage was studied in Washington during 1976, the pre-test year; 1977, the stress period; and 1978-1979, the recovery period. During the stress period, total water applied to cherry trees by daily or weekly trickle irrigation was 30,200 liters per tree at 100% of evaporation, 16,000 at 50%, and 4,300 at 15%. Total amounts applied to prunes were approximately half that of the cherry trees. Although soil moisture remained above the wilting point for 100% evaporation treatments, it reached the wilting point at 50% and 15% except near the emitters. At 15% of evaporation irrigation rate, trees survived but growth of fruit and vegetative parts was reduced and leaves dropped early in the fall. Flower bud development was not affected. Cherry trees showed dieback of peripheral branches during 1977 and 1978 and grew and fruited normally by the third year after treatment. Prunes at 15% responded similarly and recovered well by 1978. The 50% rate produced a diminished fruit yield of prunes and cherries in 1977, but yields and growth were normal the following year. (Cassar-FRC)
W82-00119

OPTIMAL DESIGN OF FURROW IRRIGATION SYSTEMS,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
J. M. Reddy, and W. Clyma.
Transactions of the ASAE, Vol 24, No 3, p 617-623, May/June, 1981. 2 Fig, 2 Tab, 11 Ref.

Descriptors: *Furrow irrigation, *Irrigation efficiency, *Optimization, Economic aspects, Farms, Costs, Design criteria, Irrigation practices, Agriculture.

Furrow irrigation system design was optimized using a combination of generalized geometric programming and the Soil Conservation Service design procedure. Water, labor, and ditch construction costs were minimized. Variables in the system included: inflow rate, time of inflow, length of run, number of lengths of run, number of sets, and number of furrows per set. The problem was formulated in terms of cost coefficients, design variables, and system physical constraints. A sample field was designed. The method delineates that particular combination of design variables that minimizes the cost while satisfying system constraints. The procedure can be used to design and operate furrow irrigation systems with efficiency and can improve on-farm water management. The design procedure could be improved by basing the design on maximum profit and by including additional decision variables. (Small-FRC)
W82-00138

FURROW IRRIGATION PRACTICES IN NORTHERN COLORADO,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
T. W. Ley, and W. Clyma.
Transactions of the ASAE, Vol 24, No 3, p 610-116, 623, May/June, 1981. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Furrow irrigation, *Performance evaluation, *Irrigation practices, Irrigation, Irrigation efficiency, Farms, Agriculture, *Colorado.

Furrow irrigation evaluations were conducted for four years on several farms in the Fort Collins and Greeley areas of Colorado. Data from six farms was used to define state-of-the-art irrigation practices and priority problems in the area. Researchers found that while marginally acceptable designs could be achieved for the longer run lengths from 400 m to 800 m, improved system performance could be attained on the run lengths of 400 m or less. Eighty-five percent of the irrigations evaluated had unacceptable performance levels. Low water application efficiencies resulted from high runoff losses. Low water requirement efficiencies resulted from cumulative soil water deficits, poor timing, and insufficient applications. Farmers tended to irrigate too soon, and under- and over-irrigation were common. Proper requirements and management could improve water application efficiencies to 75 to 95% and water requirement efficiencies to 85 to 100%. (Small-FRC)

ECONOMICS OF SNOW MANAGEMENT FOR AGRICULTURE IN THE GREAT PLAINS,
Colorado State Univ., Fort Collins. Dept. of Economics.
J. R. Snyder, M. D. Skold, and W. O. Willis.
Journal of Soil and Water Conservation, Vol 35, No 1, p 21-24, January/February, 1980. 1 Fig, 8 Tab, 5 Ref.

Descriptors: *Agriculture, *Snow management, *Cost-benefit analysis, Wheatgrasses, Barriers, Soil moisture, Wheat, Water conservation, Economic aspects, Precipitation, *Snowmelt, *Crop production.

A successful method for managing snow to increase infiltration into cropland is the use of tall (3-5 ft) wheatgrass barriers planted along topographic lines and perpendicular to prevailing winds. At Akron, Colorado, grass barriers combined with continuous cropping produced 43% more crop per acre than the traditional crop-fallow system without barriers. The amount of soil water stored averaged 150% of soil water accumulated on nearby fallow land. In Culbertson, Montana, the continuous cropping-barrier system produced an extra 15 bushels per acre of winter wheat and five bushels per acre of spring wheat compared with the conventional crop-fallow system. Net returns per acre-year were $10-$20 depending on whether the crop was originally spring or winter wheat. Profitability varied widely over the years studied, 1968-1975, depending on precipitation. Snow management practices may be of little benefit in years with low snowfall or adequate growing season precipitation. (Cassar-FRC)

FIELD TEST OF AN IRRIGATION SCHEDULING COMPUTER MODEL,
Soil and Irrigation Research Inst., Pretoria (South Africa). Dept. of Agriculture and Fisheries.
W. S. Meyer, and G. C. Green.
Water SA, Vol 7, No 1, p 43-48, January, 1981. 2 Fig, 3 Tab, 10 Ref.

Descriptors: *Irrigation requirements, *Evapotranspiration, *Computer models, Model studies, Irrigation efficiency, Transpiration, Evaporation, Mathematical models, Lysimeters, Crop yield, Wheat, Soil water, Field tests, Pretoria, *South Africa.

The United States Department of Agriculture Irrigation Scheduling Model was tested on wheat crops grown at Roodeplaat, near Pretoria, in 1979. The rate of evapotranspiration was predicted using current meteorological information. The model also utilizes a crop water use coefficient, irrigation forecasts, and soil water balance data. Results obtained during 1978 were examined to adjust the model for local conditions. Amounts of soil water depletion predicted by the model were in close agreement with those measured from soil samples. Experimental plots yielded about the same amount of grain as plots irrigated according to actual ET losses measured by weighing lysimeters stationed on the same location. However, predicted ET was higher than measured ET, so that the scheduled plots received more water than was probably required. (Geiger-FRC)

WATER APPLICATION UNIFORMITY OF HOSE TOWED TRAVELER IRRIGATORS,
Auburn Univ., AL. Agricultural Experiment Station.
R. L. Collier, and E. W. Rochester.
Transactions of the ASAE, Vol 23, No 5, p 1135-1138, 1980. 10 Fig, 1 Tab, 2 Ref.

Descriptors: *Irrigation systems, *Sprinkler irrigation, Application rates, Agriculture, Farm equipment, Irrigation engineering.

Two hose-towed traveler irrigators were studied to determine the effects of linear speed of the sprinkler carriage, reel rotation speed, flow rate, and water pressure on the uniformity of application. One irrigator was a 5-layer irrigator; the other was an irrigator with three layers of hose. Considering the diameter of the reel, a 44% theoretical increase in travel speed would be expected from beginning to end of the travel lane for the 5-layer irrigator and 24% for the 3-layer. Measured variations in travel speed averaged 42% for the 5-layer and 23% for the 3-layer. As the hose became wrapped on the reel, discharge and pressure at the nozzle decreased. Increased flow resistance caused the system to shift to a higher pump rate at a lower flow rate. The combined effect of all factors resulted in average final depths of application of 68% and 77% of initial depth for the 5-hose and 3-hose machines, respectively. (Cassar-FRC)

4. WATER QUANTITY MANAGEMENT AND CONTROL

4A. Control Of Water On The Surface

REVIEW OF REPORTS FOR FLOOD CONTROL; WESTCHESTER COUNTY STREAMS, NEW YORK.
Army Engineer District, New York.
Report, July, 1981, 75 p, 15 Fig, 12 Tab.

Descriptors: *Flood control, *Cost-benefit analysis, *Flood damage, Environmental effects, Cost analysis, Economic aspects, Disasters, *Westchester County, New York.

Numerous communities in Westchester County, New York have historically experienced serious problems due to flooding of the many streams draining the county. High intensity of prolonged rainfall such as occurred during recent floods have threatened the health and safety of the public and caused millions of dollars in damages, resulting in the county being declared a Federal Disaster Area. Flood control projects along the Saw Mill River in the Town of Chappequa and the City of Yonkers have been authorized and are presently under construction; flood control projects along the Saw Mill River in the Village of Ardsley and the Village of Elmsford - Town of Greenburgh have been authorized and are presently in the advanced engineering and design phase; and interim reports for flood control have been submitted to Congress for the Saw Mill River, Mamaroneck and Sheldrake Rivers, and the Byram River. Investigations are continuing for the Saw Mill River in the Nepera Park area of Yonkers and Nannyhagen Brook in Mount Pleasant. For the remaining areas in Westchester County, the investigations conducted in response to the study authority as well as the small flood control program have indicated that Federal flood control projects are not warranted at this time due to the lack of sufficient economic and environmental benefits to justify the cost of protective measures. USE OF RIVER WATERS THAT DID NOT REACH THE ARAL SEA AS A CONSEQUENCE OF ECONOMIC ACTIVITY DURING 1961-1975,
Akademiya Nauk SSSR, Moscow. Inst. Geografii.
E. N. Minaeva.
Water Resources (English Translation), Vol 7, No 5, p 418-422, September/October, 1980. 1 Tab, 15 Ref. Translated from Vodnye Resursy, No 5, p 82-88, September/October, 1980.

Descriptors: *Hydrologic budget, *Rivers, *USSR, Aral Sea, Irrigation, Water use, Reservoirs, Evaporation, Soil water, Water loss, Percolation, Seepage, Transpiration, Phreatophytes, Canals, Drainage water.

Intensification of irrigation agriculture in the Soviet Union resulted in the Aral Sea experiencing a shortfall of 215 cubic kilometers over the period 1961 through 1975. The State Hydrologic Institute estimated possible items of its expenditure, both lump-sum and constant, using extensive data reflecting the characteristics of the development of water management during this period. Water management developments included interbasin water transfers, creation of several shallow reservoirs on the plains, and new irrigation of large areas. All of the data were obtained by direct calculations, except for the volumes of waters filling soil pores on newly irrigated lands. Items of lump-sum water expenditure which were estimated include filling of reservoirs, filling of closed depressions with drainage waters, formation of water lenses under canals, and filling of soil pores on irrigated lands. Estimates were also developed for the following items of constant water expenditure: evaporation from irrigated lands, transpiration by phreatophytes in the zone of influence of large canals, evaporation from the water surfaces of reservoirs, evaporation from the water surfaces of depressions filled with drainage waters, and evaporation from large permanent canals. The methods of estimating each of these components of the water expenditure are described. The volumes of waters filling soil pores on newly developed lands were determined as the remainder from the calculations made. (Carroll-FRC)

A SUCCESSFUL TRANSFER,
Welsh Water Authority (Wales).
P. Goodman.
Water, No 33, p 19-20, July, 1980. 2 Fig.

Descriptors: *Water supply development, *Water transfer, *Diversion, *Wales, Diversion structures, Great Britain, Water supply, Rivers, Water conveyance, Interbasin transfers.

The small margin between existing normally available resources and actual consumption in south east Wales prompted the development of a water transfer scheme designed to meet the needs of homes and industries in South Gwent and Cardiff. Under the Wye Abstraction Scheme, 136.3 million liters per day will be diverted from the Wye and transferred across Gwent into the existing water supply there by pipeline. Additional discharges will be made from the Elan Valley reservoirs, located near the head of the Wye catchment, during periods of low flow in the river. An intake and pumping station will abstract the water from the Wye. The abstracted water will be transferred through 32 kilometers of 1.2 meter diameter steel pipeline direct to a new storage reservoir, where it can be treated for use in an area now using water from the Usk River and the Llandegfedd reservoir. Water from those sources will then be released for use in the Cardiff area. Provision will also be made for direct transmission of the water in the new

storage reservoir to treatment facilities serving the Cardiff area. The reservoir will serve as a buffer against river pollution and allow the pumps to be shut down during very dirty river conditions. The abstraction represents just over two percent of the average daily flow of the Wye and about four percent of the average flow during summer months. The intake facility has been designed to keep water velocity to a minimum to prevent fish, particularly salmon, from being drawn in and to keep silt out of the pumping station. The intermittent high and low flows in the upper Wye which will result from the abstraction scheme may tend to attract spawning fish into the river. (Carroll-FRC)

AN ANALYSIS OF RESERVOIR STORAGE CONTENTS FOR THE PROPOSED ENLARGEMENT OF BUMPING LAKE IN WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
J. H. Bartells.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $1.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 80-440, 1981. 10 p, 1 Fig, 2 Tab, 3 Ref.

Descriptors: *Reservoir storage, *Storage capacity, *Reservoir operation, *Water supply, Reservoirs, Lakes, Reservoir releases, Reservoir capacity, Reservoir yield, Reservoir fisheries, Irrigation, Water rights, Hydrologic data, Hydrographs, *Washington, *Bumping Lake.

Monthend contents of the proposed Bumping Lake enlargement in Washington were determined for the period 1917-73 by using the historic streamflow record as a basis for inflow to the reservoir and imposing certain operational requirements on reservoir releases. The operational requirements used were those set forth in the Environmental Statement that was prepared for the project by the U.S. Water and Power Resources Service (formerly the U.S. Bureau of Reclamation). The computations show that after starting with an empty reservoir on October 1, 1917, the 458,000 acre-feet capacity of the enlarged lake could be nearly full (384,000 acre-feet) on November 30, 1925, which is the starting scenario given in the Environmental Statement. From 1925 to 1973 the computations compare favorably with those shown in the Environmental Statement, with minor differences due to releases of fish enhancement water. In all cases studied, all fishwater requirements and all existing irrigation requirements were met, and generally from 30,000 to 90,000 acre-feet of extra irrigation water could be available in most years. 4B. Groundwater Management

BASIN MANAGEMENT IN THE SAN BERNARDINO VALLEY,
East San Bernardino City Water District, CA.
L. W. Rowe.
Water/Engineering and Management, Vol 128, No 5, p 79-80, 83, May, 1981.

Descriptors: *River basin development, *Watershed management, *Monitoring, Water quality, Water supply development, Water quality management, Wastewater treatment, *San Bernardino Valley, California, Groundwater management.

The San Bernardino Valley Municipal Water District manages the San Bernardino basin through monitoring, planning, and operation. Water quality data are collected for 60 key points within the district, including 13 streams and 45 wells. Basin production is monitored along with current and projected land use. Planning entails performing water supply studies for the eight service areas, including investigating the feasibility of wheeling in supplemental water or pumping groundwater from one system to another if required. Groundwater modeling is also performed. Wastewater treatment needs are being evaluated for five service areas. Operational programs include the establishment of the Santa Ana River-Mill Creek Cooperative Water Project Committee which pools area water to provide a stable water supply for all. Also, a recharge program discharges state project water into existing water conservation facilities at high elevations. The cooperative pumping agreement demonstrates the feasibility of obtaining water out of one purveyor's distribution system and conveying it to another. (Small-FRC)

AN OBSERVATION-WELL NETWORK CONCEPT AS APPLIED TO NORTH CAROLINA,
Geological Survey, Raleigh, NC. Water Resources Div.
M. D. Winner, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-106089, Price codes: A04 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-13, March 1981. 59 p, 24 Fig, 12 Tab, 11 Ref.

Descriptors: *Observation wells, *Networks, *Monitoring, *Groundwater management, Aquifers, Water level fluctuations, Discharge measurement, Geohydrologic units, Wells, Pumping, Groundwater recharge, Hydrologic data, Data collections, Data processing, *North Carolina.

A statewide observation-well program is proposed for North Carolina based on four networks of observation wells with different but clearly-defined objectives. These are referred to as the (1) climatic-effects network, (2) terrane-effects network, (3) local-effects network, and (4) areal-effects network. The characteristics of each network are related to natural and man-made stresses in aquifers, and the areas and hydrogeologic units in North Carolina where these networks are needed are identified. Formats for collection, processing, and publication of data from these networks is suggested. (USGS)

DIGITAL MODEL OF THE UNCONSOLIDATED AQUIFER SYSTEM IN THE MODESTO AREA, STANISLAUS AND SAN JOAQUIN COUNTIES, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
C. J. Londquist.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102559, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigation 81-12, July 1981. 36 p, 17 Fig, 1 Tab, 19 Ref.

Descriptors: *Model studies, *Geohydrology, *Aquifers, *Confined groundwater, Groundwater movement, Pumping, Transmissivity, Groundwater recharge, Water level, Finite difference methods, *California, Modesto, Stanislaus County, San Joaquin County, *Groundwater availability.

A digital mathematical model of the unconsolidated alluvial aquifer system in the Modesto area, Calif., has been developed which can be used to determine the effects of increased pumping and water use of future water levels in the aquifer system. The model is divided into two units. The lower unit is confined in the western part of the study area by a confining clay bed; elsewhere in this unit the aquifer is unconfined. The upper unit represents an unconfined aquifer and lies above the clay bed or its extension. Where the clay bed is absent the upper and lower units are considered as a single aquifer. The model, as calibrated, can evaluate with reasonable accuracy the effects on water levels of changing stresses and stress patterns only within the area of primary interest for the upper unit. In other areas of the upper unit and for the lower unit, predicted changes should be looked upon as, at best, representing only general trends. (USGS)
W82-00415

PROPOSED OBSERVATION-WELL NETWORKS AND GROUND-WATER LEVEL PROGRAM FOR NORTH CAROLINA,
Geological Survey, Raleigh, NC. Water Resources Div.
M. D. Winner, Jr.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price: $9.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-544, 1981. 69 p, 29 Fig, 14 Tab, 8 Ref.

Descriptors: *Observation wells, *Network design, *Monitoring, *Groundwater, Aquifers, Water level fluctuations, Discharge measurements, Geohydrologic units, Wells, Pumping, Groundwater recharge, Hydrologic data, Data collections, Data processing, *North Carolina.

An initial system of 223 observation wells is proposed for monitoring ground-water levels in North Carolina. These wells are suggested to replace and upgrade nearly 650 observation wells currently measured in separate State and Federal programs, and are arranged in four groups or networks each having specific objectives. These groups are (1) a climatic-effects network, (2) a terrane-effects network, (3) a local-effects network, and (4) an areal-effects network. Recommendations are also made regarding additional observation-well coverage in some areas of the State. Records review and network review procedures constituted the largest amount of effort in this study and required a considerable amount of organization to keep track of well records and water level data. These procedures are outlined in this report as a guide for those who are contemplating an observation-well program review. The report also contains suggested organizational contents of a data file, including

procedures for records processing, and various forms used to document the review and data-collection efforts. (USGS)

PREMINING HYDROLOGIC CONDITIONS OF FIVE SOUTHEASTERN OHIO WATERSHEDS,
Bureau of Mines, Denver, CO. Denver Research Center.
G. E. McIntosh.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-135055, Price codes: A05 in paper copy, A01 in microfiche.
In: Surface Coal Mining Reclamation Equipment and Techniques, Proceedings: Bureau of Mines Technology Transfer Seminars, Evansville, Indiana, June 3, 1980 and Denver, Colorado, June 1980. Bureau of Mines Information Circular 8823, 1980. p 60-73, 6 Fig

Descriptors: *Strip mines, *Coal mines, *Water quality, *Hydrologic data, Groundwater, *Ohio, Precipitation, Infiltration, Erosion, Land reclamation, Watersheds, Watershed management.

In Appalachia, land is being disturbed by surface mining at an accelerating rate to obtain coal for electric power production and other uses. Five watersheds, range in size from 29 to 52 acres, were selected to study the effects of mining and reclamation on hydrology and water quality. Four of these watersheds will be mined, and one will be used as a control. All the watersheds are located in east-central Ohio. The study watersheds in Coshocton County (C06 and A06) and the one in Muskingum County (M09) are located in the Muskingum River Basin. The two Jefferson County sites (J11 and J08) drain into small tributaries of the Ohio River. On each watershed soil and vegetation surveys were run, and geologic cores were obtained in order to determine baseline physical conditions. Weather stations were set up to monitor precipitation, temperature, relative humidity, wind speed, and solar radiation. Infiltration tests, surface water quality and quantity measurements, and ground water studies are being conducted. In addition to the monitoring of the watersheds, erosion and treatment plots have been set up at three of the mine sites. (Moore-SRC)

PHYSICAL EFFECTS OF VEHICULAR DISTURBANCES ON ARID LANDSCAPES,
Stanford Univ., CA. Dept. of Applied Earth Sciences.
R. M. Iverson, B. S. Hinckley, R. M. Webb, and B. Hallet.
Science, Vol 212, No 4497, p 915-917, May, 1981. 1 Fig, 1 Tab, 20 Ref.

Descriptors: *Arid-zone hydrology, *Rainfall infiltration, *Soil erosion, *Surface runoff, Arid lands, Erosion, Erosion control, Infiltration capacity, Soil porosity, Mathematical studies, Runoff, Overland flow, Soil compaction, *Off-road vehicle effects.

The arid lands of the Southwestern part of the United States are increasingly being used for recreation by off-road vehicles. Such vehicles have been shown to cause damage to arid land hydrology by increasing the amount and frequency of water runoff and erosion by reducing soil porosity, infiltration capacity, and hydraulic resistance to overland flow. Natural surface stabilizers are also disrupted by vehicular travels. In 50 rainfall simulation tests, vehicle-used plots had about 5 times more runoff and 10-20 times greater sediment yield than adjacent unused plots. In a desert environment, such effects may occur even when use of off-road vehicles is light. Recovery times from vehicular damage are estimated to be nearly 100 years. Erosion rates were calculated from multivariate statistical analyses using 22 experimental factors. The character of the rainfall was identified as the most important variable in predicting increases in erosion. (Geiger-FRC)

SLASH TREATMENT AFTER CLEARCUTTING LODGEPOLE PINE AFFECTS NUTRIENTS IN SOIL WATER,
Utah State Univ., Logan. Dept. of Forestry and Outdoor Recreation.
G. E. Hart, N. V. DeByle, and R. W. Hennes.
Journal of Forestry, Vol 79, No 7, p 446-450, July, 1981. 1 Fig, 1 Tab, 14 Ref.

Descriptors: *Nutrients, *Forest soils, *Clear-cutting, Forests, Pine trees, Forest management, Cutting management, Coniferous trees, Industrial wastes, Organic wastes, *Waste disposal, Soil solution, Mulching, Incineration, Sodium, Phenols, Potassium, Magnesium, Calcium, Nitrate, Soil water.

Harvesting of old-growth coniferous forests in the northwest United States produces large volumes of organic debris which must be reduced to lower fire hazard, control insects, improve seedbeds, provide access, and/or ameliorate appearance. Changes in soil solution chemistry resulting from four slash disposal methods employed after clearcutting of old-growth lodgepole pine were investigated. The slash disposal methods used included nearly complete removal, spreading the residue as chips, broadcast burning, and windrow burning. Soil solutions from the areas which had been clearcut had slightly higher concentrations of sodium, potassium, magnesium, calcium, and nitrate than did those from an adjacent unharvested forest area. Effects on stream water resulting from leaching or runoff would be negligible and difficult to detect. High concentrations of nitrate-nitrogen were found in the intensively burned areas beneath windrows and following broadcast burning. Use of the residue as a mulch after near-complete harvesting resulted in a flush of phenolic compounds into the soil solution during the first post-treatment year. Phenol concentrations in soil solutions after mulching were significantly higher than acceptable levels for fish habitats. Broadcast burning apears to be preferable to windrow burning because it diffuses effects on soil and soil water over the entire area. Chemical composition of soil water appears to be least affected by residue disposal practices that cause minimal mechanical disturbance and minimal incorporation of organic matter into soil surfaces. USE OF FLOW-DURATION CURVES TO EVALUATE EFFECTS OF URBANIZATION ON STREAMFLOW PATTERNS ON LONG ISLAND, NEW YORK,
Geological Survey, Syosset, NY. Water Resources Div.
K. R. Prince.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-114307, Price codes: A02 in paper copy, A01 in microfiche.
Geological Survey Water-Resources Investigations 80-114, 1981. 19 p, 4 Fig, 4 Tab, 15 Ref.

Descriptors: *Flow duration, *Urbanization, *Streamflow, *Urban runoff, Urban hydrology, Base flow, Storm runoff, Water level, Pumping, Water supply, Sewer systems, Population dynamics, *New York, *Long Island, Nassau County, Suffolk County, Peak flow.

Streamflow patterns on Long Island, N.Y., have been changing over the last three decades in response to eastward population growth and urbanization. Flow-duration curves for nine streams in Nassau and Suffolk Counties indicate that, during this time, streams in urbanized areas have had increased peak flows and decreased base flows, whereas streams in sparsely populated areas have shown little or no change. The increase in peak flows reflects the greater volume of storm runoff from impermeable surfaces such as roads, parking lots, and roofs. The decrease in base flows results from the lowering of groundwater levels, principally by sanitary sewerage and extensive pumping for public water supply. At East Meadow Brook, in a sewered, densely populated area of Nassau County, peak flows (1-percent duration) increased by 41% during 1946-74, and base flows (98-percent duration) decreased by 99%. In contrast, peak and base flows of Carmans River, in a largely undisturbed, rural area of Suffolk County, showed fluctuations no greater than 19% during the same period. (USGS)

4D. Watershed Protection

TERRACE PLANNING CRITERIA FOR RUNOFF CONTROL FOR DEEP LOESS SOIL,
Harza Engineering Co., Chicago, IL.
P. Jacobson.
Transactions of the ASAE, Vol 24, No 3, p 699-704, May/June, 1981. 4 Fig, 8 Ref.

Descriptors: *Runoff, *Terracing, Land forming, Loess, Contour terracing, Geological terraces, Agriculture, Farming, Erosion, *Erosion control.

Procedures used to develop a water control system adapted for ease in farming are described. The system was based on 19 years of experience. Adoption of these procedures should alleviate most objections to terraces and other control measures. Specific planning criteria are to be used for: lands having slopes less than 6% with deeply entrenched waterways; lands of uniform slopes with minor waterway entrenchment; lands with slopes over 6% with deeply entrenched waterways spaced 120 meters or less horizontally; lands having slopes over 6% with deeply entrenched waterways spaced over 120 meters apart; and relatively flat, moderately rolling upland areas which are dissected by a few deeply entrenched waterways. The terrace planning criteria outlined for these various slopes and topographies proved to offer fairly straight row alignment on much of the experimental farm. This would not have been the case with conventional terrace layouts. This sets the stage for a practically erosion-free surface obtained through the use of terraces and fills. To maintain fertility and crop yields across the terrace interval, steep backslope terraces and gully fills designed for subsequent benching will necessarily be limited to deep soils. (Baker-FRC)

PROTECTING AGRICULTURE'S NATURAL RESOURCE BASE,
Iowa State Univ., Ames.
J. F. Timmons.
Journal of Soil and Water Conservation, Vol 35, No 1, p 5-11, January/February, 1980. 3 Tab, 28 Ref.

Descriptors: *Erosion control, *Water pollution prevention, *Soil conservation, *Agriculture, Iowa, Resources management, Water quality, Suspended sediments, Economic aspects, Cultivated lands, Conservation, Grain crops.

Soil erosion and associated water quality problems may replace petroleum as the nation's most critical natural resource problem. One factor influencing soil erosion on the individual farm level is the tendency to maximize immediate income at the expense of long term erosion control measures or of water quality at a distant site. On the national or international scale, increased demand for agricultural products and limitations to the capacity to produce these crops contribute to soil erosion. Some productive agricultural practices are discouraged by water quality standards imposed on suspended silt and chemical residuals. At the same time, increasing grain exports, changing meadows and forests to more erosion-susceptible agricultural use, and decreasing funds for soil conservation have compounded the erosion problem. Strategies for reducing soil losses are: (1) research and education, (2) the 'red ticket' strategy to require the unwilling few to submit to the majority will, (3) the 'green ticket' strategy, providing financial incentives to conserve soil, (4) complementary controls and incentives, (5) public investments on private land, (6) cushioning impacts of grain exports, (7) soil conservation districts, and (8) integrating soil erosion control with food assistance policies. Some of these strategies are illustrated by examples of court decisions and activities in Iowa. (Cassar-FRC)

Wastewater from such sources as refineries, shale-oil recovery plants, coal-conversion operations, chemical plants, ships, offshore drilling platforms, petroleum-handling facilities, and other industries may contain harmful quantities of hydrocarbon materials in suspension. While installation and operation of wastewater treatment processes is a major step toward elimination of hydrocarbon pollution, to achieve maximum effectiveness it is necessary to monitor the effluent of a treatment process to insure that the system is functioning correctly. A new oil-in-water monitor technique brings together for the first time reverse-phase liquid chromatography and fiber optics. A special organophilic optical fiber, created by a chemical treatment process routinely used in reversed-phase liquid chromatography, collects and concentrates suspended hydrocarbon materials on its surface. Various methods of chemically treating an optical fiber and various treatment reagents were evaluated. For such aromatic hydrocarbons as n-hexylbenzene, cyclohexylbenzene, heptadecylbenzene, 3,3'-dimethylbiphenyl, and 1-phenylnaphthalene and for crude oil, detection thresholds of less than 3 mg/l were observed, and system reponse was linear over a contaminant concentration range of greater than 2.5 decades (greater than 300:1). Data indicate that the high end of the range can be extended if desired. (Moore-SRC)

DETERMINATION OF PRIORITY POLLUTANT PHENOLS IN WATER BY HPLC,
Altex Scientific, Berkeley, CA.
P. A. Realini.
Journal of Chromatographic Science, Vol 19, No 3, p 124-129, March, 1981. 6 Fig, 5 Tab, 13 Ref.

Descriptors: *Phenols, *Water analysis, Chromatography, Chemical analysis, Wastewater analysis, Pollutant identification.

An HPLC method is described for the analysis of waste water and drinking water for nanogram levels of phenols specified by the United States Environmental Protection Agency as priority pollutants. This classification includes: phenol, p-nitrophenol, o-chlorophenol, 2,4-dinitrophenol, o-nitrophenol, 2,4-dimethylphenol, 4-chloro-m-cresol, 2,4-dichlorophenol, 4,6-dintro-o-cresol, 2,4,6-trichlorophenol, and pentachlorophenol. Methylene chloride was used as the solvent for the concentration-extraction of phenols from water samples. After extraction the pH was adjusted to 14. Further extraction was carried out with methylene chloride. Both acidic and basic extracts were then combined and evaporated to dryness with a stream of nitrogen in a water bath. The sample was redissolved in 1 ml of acetonitrile and 10 microliters was injected directly onto the column. The calibration curve was linear between 1 ng and 50 ng. Extraction of phenols from waste water was also achieved with methylene chloride. The use of an ion-pair extraction in basic solution gave good recoveries, and the use of reversed-phase chromatography gave excellent separation of the priority pollutant phenols. (Baker-FRC)

ORGANIC MICROPOLLUTION INDICES OF EFFLUENTS AND RENOVATED WATERS,
Technion-Israel Inst. of Tech., Haifa. Environmental and Water Resources Engineering.
M. Rebhun, and J. Manka.
Water Research, Vol 15, No 7, p 789-801, July, 1981. 10 Fig, 4 Tab, 15 Ref.

Descriptors: *Water analysis, *Organic compounds, *Effluents, *Wastewater treatment, Pollutant identification, Trace levels, Solvents, Secondary wastewater treatment, Advanced wastewater treatment, Gas chromatography, Lime.

Solvent-extractable organics (SEO) were characterized in secondary and tertiary effluents by column fractionation, elution with solvents of different polarity, and gas chromatography. The most efficient solvent combination was benzene followed by chloroform. Diethyl ether alone was also a satisfactory eluant. In secondary effluents the SEO were 45% polar, 32% nonpolar, and the remainder, intermediate in polarity. Lime treatment removed 37% of the total SEO, 63% of the nonpolar compounds, 91% of the medium polarity compounds, and 53% of the polar compounds. After-lime polishing pond detention treatment removals were 68% of total SEO, 75% of nonpolar, 96% of medium polar, and 64% of polar. 74% of lindane and 97.5% of aldrin, respectively, were removed by after-lime flocculation and 97.4% and 100%, respectively, by after-lime flocculation plus detention. Electron capture detector chromatography indicated an 80% removal of organics, near that of the medium polarity compounds. Flame ionization detection indicated a 69% removal, similar to the total SEO removal. These methods may be useful as rapid and representative indicators of organic micropollutants in effluents and renovated waters. (Cassar-FRC)

THE EFFECT OF CENTRIFUGATION ON THE SUSPENDED PARTICLES OF RIVER WATERS,
Birzeit Univ., West Bank (Israel). Dept. of Chemistry.
R. Salim, and B. G. Cooksey.
Water Research, Vol 15, No 7, p 835-839, July, 1981. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Centrifugation, *Suspended solids, *Particle size, Particulate matter, Natural waters, Water analysis, Aggregates, *Clyde River, Galsgow, *Scotland.

Particle size distribution in water from the Clyde River, Glasgow, differed when measured by 2 methods: Coulter counter and centrifugation. This is probably due to agglomeration of fine particles during centrifugation. The weight and the surface area of particles separated by centrifugation at constant centrifugal force were linearly related to the reciprocal square root of time of centrifugation. Maximum efficiency of centrifugation to separate particles was 30 min at 5720 g centrifugal force and 22 min at 7000 g centrifugal force. About 90% by weight of particles 5 micrometers or larger in diameter were separated from the river water. The centrifugation method may be usable for separation of particulate matter in natural water samples to differentiate between labile and adsorbed trace metals. (Cassar-FRC)

USE OF THE ELECTROLYTIC RESPIROMETER TO MEASURE BIODEGRADATION IN NATURAL WATERS,
Procter and Gamble Co., Cincinnati, OH.
R. J. Larson, and R. L. Perry.
Water Research, Vol 15, No 6, p 697-702, June, 1981. 4 Fig, 4 Tab, 13 Ref.

Descriptors: *Biodegradation, *Surfactants, *Respirometer, Degradation, Natural waters, Measuring instruments, Fate of pollutants, Linear alkyl sulfonates, Alkylbenzene sulfonates, Ohio River.

The electrolytic respirometer was used to study the rate and extent of biodegradation of anionic, cationic, and nonionic surfactants in Ohio River water. The lowest concentration which could be tested was 5 mg per liter if the test material contained 60-80% carbon. Kinetics of oxygen uptake during degradation of the three surfactants studied, linear alkylbenzene sulfonate (LAS), cetyltrimethylammonium chloride (CTAC), and linear alcohol ethoxylate (LAE), were similar to those observed for glucose. Rates of LAE degradation were a saturable function of LAE concentration and did not increase proportionately with

concentration. CTAC degradation was a linear function of CTAC concentration, and saturation effects were not seen up to levels of 40 mg per liter. Beyond this point degradation decreased until 80 mg per liter, where it was totally inhibited. LAS degradation rates were proportional to concentration at 5 and 10 mg per liter and decreased sharply at 20 mg per liter. The surfactant was toxic to microorganisms at higher concentrations. If velocity curves are obtained, the rate data can be extrapolated to the lower surfactant concentrations normally encountered in natural waters. The electrolytic respirometer is useful to measure biodegradation of organic compounds where specific analytical methods are unavailable. (Cassar-FRC)

INTERFERENCE OF SULPHIDE IN INORGANIC PHOSPHATE DETERMINATION IN NATURAL WATERS,
Nederlands Inst. voor Onderzoek der Zee, Texel.
V. N. De Jonge, and L. A. Villerius.
Marine Chemistry, Vol 9, No 3, p 191-197, June, 1980. 3 Fig, 1 Tab, 23 Ref.

Descriptors: *Spectrophotometry, *Phosphates, *Chemical interference, *Sulfides, Water analysis, Antimony, Natural waters.

The interference of sulfide with the assay of inorganic phosphate is caused by antimony, one of the reagents. There can be various effects on the absorption spectrum, depending upon the concentrations of antimony and sulfide. Different antimony-sulfide compounds are formed, and the spectrum of phosphomolybdenum-antimony blue is replaced by that of pure phosphomolybdenum blue. The disturbance can be prevented through the method proposed by Murphy and Riley, which uses a higher antimony concentration. An antimony concentration of 100 micromol/liter makes the PO4-P determination independent of sulfide interference when applied to oceanic and coastal waters. If sulfide concentrations are expected to be higher than 200 micromol/liter, it is desirable to remove most of the sulfide by adding 1 ml of 6 N sulfuric acid to a 100 ml water sample, followed by bubbling with nitrogen for 15 min. SOLUTION SPECIES OF PLUTONIUM IN THE ENVIRONMENT,
Battelle Pacific Northwest Lab., Richland, WA.
D. Rai, R. J. Serne, and J. L. Swanson.
Journal of Environmental Quality, Vol 9, No 3, p 417-420, July-September, 1980. 1 Fig, 2 Tab, 23 Ref.

Descriptors: *Plutonium, *Thermodynamics, Oxidation, Radioactive wastes, Adsorption, Precipitation, Environment, *Polutant identification.

Experimental data is presented that demonstrates the presence of Pu(V) in solutions in equilibrium with solid Pu(IV) hydroxide under conitions similar to those expected in the environment. The presence of Pu(V) in solutions contacting PuO2 is also inferred from the data. An Eh-pH diagram showing the stability fields of different solution species of Pu was developed. Recently evaluated thermodynamic data was used to develop the diagram. From this diagram it was concluded that the expected predominant species under relatively reducing environmental conditions would be Pu(III), and that Pu(V) would be the expected species to predominate under relatively oxidizing environmental conditions. Measurement was made of the Eh-pH values of 0.0015M calcium chloride solutions contacting Pu(IV) hydroxide and PuO2(s), they fell in or near the region of uncertainty between the calculated Pu(III) and Pu(V) stability fields. Solvent extraction tests were performed that demonstrated the absence of Pu(IV) in these solutions. Spectrophotometric tests demonstrated the absence of Pu(VI) in these solutions and indirectly demonstrated that Pu(V) was the predominant species. (Baker-FRC)

SORPTION-DESORPTION OF LINDANE BY ANAEROBIC AND AEROBIC SOILS,
Central Rice Research Inst., Cuttack (India).
P. A. Wahid, and N. Sethunathan.
Journal of Agricultural and Food Chemistry, Vol 28, No 3, p 623-625, May/June, 1980. 2 Fig, 2 Tab, 15 Ref.

Descriptors: *Pesticides, *Sorption, Leaching, Soil properties, *Lindane, Agricultural chemicals, Organic compounds, Pokkali soils, Laterite soils, Alluvial soils, Rice, Flooding, Tropical regions.

Sorption of lindane by aerobic soils and by soils prereduced by 30-day flooding was studied. Three soil types were studied: alluvial, laterite, and pokkali. No increase in soil potentials occurred following 30 min of equilibration of anaerobic soils with lindane in the sealed system used. Anaerobic soils sorbed relatively less lindane than the aerobic soils. Alluvial soil, having the least organic matter content, showed the largest difference relative to organic matter, followed by laterite soil and organic matter-rich pokkali soil. To study desorption, lindane sorbed by 30-day flooded soils during 30 min of equilibration was desorbed by equilibrating with water for 30 min. During equilibration for desorption, the redox potentials increased from -60, -160, and -220 mV to 120, -10, and -220 mV in alluvial, laterite, and pokkali soils, respectively. However, these potentials were clearly lower than those of the respective aerobic soils, with values ranging from 200 to 260 mV. No appreciable difference in desorption occurred despite the state of redox conditions of the soils. As in aerobic soils, an inverse relation between organic matter and desorption of lindane was noted in anaerobic soils as well with least desorption from organic-matter-rich pokkali soil. It is suggested that the reduction of the soil following flooding does not affect its pesticide desorbing power. The decreased sorption of lindane by anaerobic soils may influence its bioactivity and environmental transport, especially in tropical rice growing areas with soils low in organic matter and high in iron oxides. BACTERIAL CONTAMINATION OF DRINKING WATER SUPPLIES IN A MODERN RURAL NEIGHBORHOOD,
Oregon State Univ., Corvallis. Dept. of Microbiology.
K. G. Lamka, M. W. LeChevallier, and R. J. Seider.
Applied and Environmental Microbiology, Vol 39, No 4, p 734-738, April, 1980. 1 Fig, 3 Tab, 27 Ref.

Descriptors: *Bacteria, *Drinking water, *Rural areas, Well water, Coliforms, Staphylococcus aureus, Water quality, Public health.

An intensive bacteriological investigation was made of the incidence, numbers, and bacterial species present in drinking water, primarily well water, in a rural community. Water serving 78 households was sampled on six occasions during a 15-month period. Water was tested for coliforms, fecal coliforms, Staphylococcus aureus, and standard plate count bacteria. On at least one occasion, more than one-third of the water supplies were judged unsatisfactory on the basis of standard plate counts over 10,000/ml and the presence of coliforms, fecal coliforms, and/or S. aureus. The most frequently isolated total coliforms were Citrobacter freundii, Klebsiella pneumoniae, and Escherichia coli. At least twelve other genera of bacteria were identified. Coliform contamination was higher after rainfall, while standard plate counts were higher during warm weather. The coliform contamination was probably due to leakage of surface water into improperly sealed wells while high standard plate counts may have resulted from the lack of chlorination to control microbial regrowth during warm weather. INFLUENCE OF ESTUARINE SEDIMENT ON VIRUS SURVIVAL UNDER FIELD CONDITIONS,
Baylor College of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
R. L. LaBelle, and C. P. Gerba.
Applied and Environmental Microbiology, Vol 39, No 4, p 749-755, April, 1980. 3 Fig, 2 Tab, 25 Ref.

Descriptors: *Viruses, *Sediments, *Adsorption, *Estuaries, Canals, Seawater, Poliovirus, Field tests, Survival.

Field studies were performed to determine whether sediment exhibits a protective effect on virus survival, as it has in laboratory studies. Experiments were carried out in two canals exposed to sewage using two types of survival chambers: cellulose dialysis tubes or a plexiglass chamber designed to support diffusion membranes. Virus inactivation rates for poliovirus 1 and echovirus in seawater were similar for the two chambers. Virus adsorption to sediment greatly increased survival time. For virus adsorbed to sediment at a relatively nonpolluted site, the time required to inactivate 99% of poliovirus increased from 1.4 days to 6.0 days. At a more polluted site, poliovirus inactivation time was increased from about 1 h to 4.25 days by adsorption to sediment. Thus, virus association with estuarine sediment tends to prolong its survival in a seawater environment, and sediment analysis should be considered when determining viral populations. (Small-FRC)

METHOD FOR RECOVERING VIRUSES FROM RIVER WATER SOLIDS,
Environmental Monitoring and Support Lab., Cincinnati, OH.
G. Berg, and D. R. Dahling.
Applied and Environmental Microbiology, Vol 39, No 4, p 850-853, April, 1980. 5 Tab, 8 Ref.

Descriptors: *Suspended solids, *Rivers, *Viruses, Enteroviruses, Adsorption, Assay, Costs, Performance evaluation, Pollutant identification.

A method was developed for recovering poliovirus 1 that was adsorbed to river water solids. Small numbers of virions were eluted by mixing the solids for 30 min with a 10% solution of beef extract that contained sufficient Na2HPO4 to bring the molarity of the salt to 0.05 and sufficient citric acid to bring the pH to 7. Using this technique, many different enteroviruses have been recovered from river water solids. The method is not very practical when small numbers of viruses are to be recovered because it requires large numbers of cell cultures for assay. The organic flocculation technique of Katzenelson et al can be incorporated to save costs, but there is some loss of efficiency. Using the beef extract method, 39 to 63% of the polioviruses that had been adsorbed were recovered. A technique such as this is important because the number of virions recovered from solids in the river waters often exceeds the number recovered from the waters alone. (Small-FRC)

COMPARISON OF NINE BRANDS OF MEMBRANE FILTER AND THE MOST-PROBABLE-NUMBER METHODS FOR TOTAL COLIFORM ENUMERATION IN SEWAGE-CONTAMINATED DRINKING WATER,
Health and Welfare Canada, Ottawa (Ontario). Health Protection Branch.
R. S. Tobin, P. Lomax, and D. J. Kushner.
Applied and Environmental Microbiology, Vol 40, No 2, p 186-191, August, 1980. 3 Tab, 36 Ref.

Descriptors: *Monitoring, *Water quality, Filtration, *Membrane filters, Filters, Membrane proc-

esses, Chlorination, Drinking water, *Coliforms, Bacteria, Sewage bacteria, Wastewater pollution.

The possibility of significant differences existing among membrane filters in their ability to enumerate chlorine-stressed coliforms in sewage-contaminated drinking water was examined. Results obtained with the membrane filtration (MF) method are compared with those obtained by the most-probable-number (MPN) method. Aerated Ottawa tap water was used as the challenge water. To produce a sewage-contaminated water for test purposes, 2-10 ml of the supernatant of settled raw sewage was added to 6 liters of tap water to produce a total coliform density of 15,000 to 20,000 colonies/100 ml before chlorination. Chlorination of the contaminated samples was performed with the addition of 0.8 mg of available chlorine/liter using a contact time of 30 min at room temperature. Nine different brands of membrane filter were compared in the MF method. Significant differences were noted among membranes in four of the six experiments, with two-to four-times higher recoveries between the membranes at each extreme of recovery. When results from the membranes with the highest total coliform recovery rate were compared with the MPN results, the MF results were significantly higher in one experiment and equivalent to the MPN results in the other five experiments. A comparison was made of the species enumerated by these methods. In general the two methods enumerated a similar spectrum of organisms, with some indication that the MF method was subject to greater interference by Aeromonas. (Baker-FRC)

DETERMINATION OF TRACE QUANTITIES OF DIMETHYLSULFOXIDE IN AQUEOUS SOLUTIONS,
Florida State Univ., Tallahassee. Dept. of Oceanography.
M. O. Andreae.
Analytical Chemistry, Vol 52, No 1, p 150-153, January, 1980. 2 Fig, 2 Tab, 14 Ref.

Descriptors: *Water analysis, *Solvents, Organic compounds, *Dimethylsulfoxide, Sulfoxides, Industrial wastewaters, Rain, Photometry, Flame photometry, Gas chromatography.

The determination of dimethylsulfoxide (DMSO) at the nanogram level in aqueous solutions is described. After removal of dissolved volatile sulfur compounds by sparging with helium, DMSO is reduced to dimethylsulfide with sodium borohydride or chromium(II) chloride. The dimethylsulfide is stripped from the solution with a stream of helium and trapped on a chromatographic packing in a U-tube immersed in liquid nitrogen. After gas chromatographic separation from potentially interfering compounds, the dimethylsulfide is measured by a flame photometric sulfur detector and/or a flame ionization detector. The detection limit of the method is 1 ng S(DMSO) per sample, which corresponds to 0.02 micrograms S(DMSO)/liter. Precision is 5-10%, depending which variant of the method is used. The method has been used for the determination of DMSO in a variety of samples, including seawater, freshwater, rain, and phytoplankton culture solutions. DMSO appears to be a common constituent in natural waters. Its occurrence in seawater is restricted to the zone of light penetration. It may occur as an end product of algal metabolism. The occurrence of DMSO in rain may be due either to the release of this substance from the biosphere into the atmosphere or to the atmospheric oxidation of DMS to DMSO. (Baker-FRC)

REDOX STABILITY OF INORGANIC ARSENIC(III) AND ARSENIC(V) IN AQUEOUS SOLUTION,
North Dakota State Univ., Fargo. Dept. of Chemistry.
D. E. Tallman, and A. U. Shaikh.
Analytical Chemistry, Vol 52, No 1, p 196-199, January, 1980. 1 Fig, 3 Tab, 7 Ref.

Descriptors: *Arsenic, *Sample preservation, *Water analysis, Chemical analysis, Water sampling, Arsenicals, Arsenic compounds.

The stability of inorganic As(III) and As(V) in aqueous solution was re-examined. The findings indicate that solutions containing inorganic As(III) or (V) at ppb levels can be retained for at least three weeks without significant interconversion of As(III) and As(V) or loss of total arsenic. This conclusion pertained to water samples from natural sources as well as laboratory prepared standards. The samples were stored in glass with minimum precautions to exclude oxygen or other redox promoting contaminants. These findings are offered in argument against another report wherein it is stated that As(III) at the ppb level in aqueous solution undergoes a spontaneous oxidation to As(V) with essentially complete conversion occurring within one week for solutions less than 100 ppb in As(III). MEASUREMENT OF THE SOLUBILITIES OF SLIGHTLY SOLUBLE ORGANIC LIQUIDS IN WATER BY ELUTION CHROMATOGRAPHY,
National Bureau of Standards, Washington, DC. National Measurement Lab.
F. P. Schwarz.
Analytical Chemistry, Vol 52, No 1, p 10-15, January, 1980. 2 Fig, 4 Tab, 20 Ref.

Descriptors: *Organic compounds, *Solubility, Chemical analysis, *Chromatography, Water analysis, Water pollution control.

A solubility measurement method was examined which is simple and may well meet the ideal criteria of high sensitivity and nonspecificity needed to determine the solubilities of organic liquids in water. The method is based on liquid phase elution chromatography. The solute is the stationary phase, and water is the mobile phase. A transparent column is packed with an inert support coated with a known amount of the solute and then water is forced through the column. As the total volume of water flowing through the column increases, a solute depleted zone, different in color from the stationary phase, develops and increases in length. The solubility is calculated from the amount of solute removed from the column, i.e., the length of the solute depleted zone and the volume of water passed through the column. This method has been applied to the determination of ten different organic solutes to evaluate its sensitivity and specificity. In these determinations the method was shown to be nonspecific, sensitive to the ppm level, accurate, and fairly precise. (Baker-FRC)

CONSECUTIVE AMPEROMETRIC TITRATIONS FOR CALCIUM AND MAGNESIUM,
Allied Chemical Corp., Idaho Falls, ID.
L. L. Jackson, J. Osteryoung, J. O'Dea, and R. A. Osteryoung.
Analytical Chemistry, Vol 52, No 1, p 71-75, January, 1980. 3 Fig, 5 Tab, 17 Ref.

Descriptors: *Water analysis, *Metals, *Calcium, *Magnesium, Titration, Polarographic analysis, Chemical analysis.

A procedure is described for the measurement of both calcium and magnesium in a single aliquot. In this procedure the calcium is first titrated with ethylene glycol bis(beta-aminoethyl ether)-N,N,N,N'-tetraacetic acid (EGTA), and then magnesium is titrated with ethylenediaminetetraacetic acid (EDTA). 1,2-Diaminocyclohexane-N,N,N,N'-tetraacetic acid (DCTA) was also examined as a possible titrant for magnesium. The end point in each titration is determined by amperometric detection of the excess chelate at a dropping mercury electrode. Both the normal pulse and differential pulse amperometric modes were used, in contrast to the dc amperometric mode which has been employed in other work. The methods were tested at calcium and magnesium levels of 1-0.001 mF. Analyses were also done at ratios of calcium to magnesium from 100:1 to 1:100. These amperometric techniques were then applied to a variety of natural samples. It was found that copper and nickel could effectively be masked with tetraethylenetriamine (TRIEN), an excess of which did not have an adverse effect on the calcium and magnesium titrations in the normal pulse mode. The mode appears attractive for analysis of natural waters and other sample types, particularly in the automated mode. (Baker-FRC)

A DIRECT DIFFERENTIAL PULSE ANODIC STRIPPING VOLTAMMETRIC METHOD FOR THE DETERMINATION OF THALLIUM IN NATURAL WATERS,
Geological Survey, Denver, CO.
J. E. Bonelli, H. E. Taylor, and R. K. Skogerboe.
Analytica Chimica Acta, Vol 118, No 2, p 243-256, August, 1980. 5 Fig, 4 Tab, 43 Ref.

Descriptors: *Thallium, *Water analysis, Chemical analysis, Surface water, Water pollution control, Fuel, Voltammetry, Anodes, Electrodes, Insecticides.

Routine thallium determinations in natural water samples submitted to the US Geological Survey Central Laboratory in Denver are being performed using a direct differential pulse anodic stripping voltammetric method (DPASV). This method requires no preconcentration, or at the most preconcentration for one hour and a sample volume of 25 ml, and provides a detection limit of 10 mg thallium per liter. This limit may be extended by appropriate alteration of experimental parameters or by the use of preconcentration steps. DPASV at the hanging mercury drop electrode and at the mercury film electrode is used in the concentration ranges 0.5-100 micrograms thallium per liter and 0.01-10 micrograms thallium per liter, respectively. Quantification is aided by the technique of standard additions. The response of the method is optimized for typical natural surface water matrices. An intercomparison of thallium determinations performed by the two anodic stripping methods and electrothermal-atomization atomic absorption spectrometry on normal and thallium-spiked surface water samples demonstrates equivalent accuracy within the range where atomic absorption is applicable. The method appears free from serious interferences. (Baker-FRC)

IMPROVED METHOD AND TEST STRATEGY FOR RECOVERY OF ENTERIC VIRUSES FROM SHELLFISH,
New Hampshire Univ., Durham. Dept. of Microbiology.
T. G. Metcalf, E. Moulton, and D. Eckerson.
Applied and Environmental Microbiology, Vol 39, No 1, p 141-152, January, 1980. 11 Tab, 24 Ref.

Descriptors: *Viruses, *Shellfish, Enteric bacteria, Filters, Enteroviruses, Membrane filters, Filtration.

A virus monitoring strategy is presented for recovery of enteric viruses from each of three commercially important shellfish species. The monitoring strategy includes the development of a single recovery method equally effective with oysters and hard- and soft-shell clams and identification of the test strategy needed for effective use of the improved method for recovery of low numbers of enteric viruses from each of these species. Effective recovery of virus depended as much upon details of the test strategy adopted for use of the improved method with each species as on the method itself. The most important test details involved sample composition, pool size, and method of use of cell culture. Recovery sensitivity measured permitted detection of 25 to 3 plaque-forming units of enteroviruses and 100 to 27 plaque-forming units of reovirus through their recovery in cell culture, with effectivenesses averaging 64 and 46%, respectively. Test samples prepared by the improved recovery method were virtually cytotoxicity free. Optimal recovery of virus on 45-square centimeter cell culture monolayers was obtained with 1-ml inocula adsorbed for 2 hr. The most effective recovery of virus from shellfish samples was made by a sequential adsorption procedure which allowed equal exposure to an entire

sample to each of two or more cell cultures. Removal of nonviral contaminants from test samples by antibiotic treatment was preferable to the use of ether or membrane filtration procedures. (Baker-FRC)

ENUMERATION OF POTENTIALLY PATHOGENIC BACTERIA FROM SEWAGE SLUDGES,
Texas Univ. Center for Applied Research and Technology at San Antonio.
D. J. Dudley, M. N. Guentzel, M. J. Ibarra, B. E. Moore, and B. P. Sagik.
Applied and Environmental Microbiology, Vol 39, No 1, p 118-126, January, 1980. 1 Fig, 5 Tab, 37 Ref.

Descriptors: *Bacteria, *Sludge, *Wastewater, Human diseases, *Land disposal, Salmonella, Staphylococcus, Mycobacterium, Shigella, Bacterial analysis, Sampling, Mixing.

Methodologies are presented that can provide quantitative data on the population densities in sludge of fluorescent Pseudomonas species, Staphylococcus, Mycobacterium, Clostridium, and Klebsiella, and semiquantitative data on Shigella and Salmonella. Enterobacteriaceae and oxidase-positive enteric organisms were quantitated using a multi-media rapid identification system. Determinations of routine indicator organisms were also performed on the sludges for the purpose of comparison with published studies on wastewater. Sludges used in the study were obtained from the Rilling Road Regional Wastewater Treatment Plant in San Antonio, Texas, as either primary or anaerobically digested sludges. Wasted secondary sludge samples from an activated sludge treatment process were collected at Kerrville, Texas. Bacterial surveys were performed on sludges undergoing land application at sites in the United States. The procedures compared included vortex mixing at high speed for 2 min of 20 ml of sludge containing about 1 g of sterile 3-mm glass beads in 50-ml centrifuge tubes, homogenization at high speed in a Waring blender, sonication at various wattage outputs, and direct plating without treatment. Sonication at all wattage levels was found to be bactericidal. Sludge sonicated at an output of 66 W yielded the highest recoveries from sludges that were sonicated. The best recovery of viable organisms was obtained in samples dispersed by vortex mixing with glass beads. Therefore, this method was selected as the sludge handling procedure before any bacterial analyses on subsequent sludge samples. (Baker-FRC)

TECHNIQUE FOR DETERMINING TOTAL BACTERIAL VIRUS COUNTS IN COMPLEX AQUEOUS SYSTEMS,
Clemson Univ., SC. Dept. of Microbiology.
D. L. Ewert, and M. J. B. Paynter.
Applied and Environmental Microbiology, Vol 39, No 1, p 253-260, January, 1980. 2 Fig, 3 Tab, 21 Ref.

Descriptors: *Viruses, *Isolation, Clarification, Bacteriophages, Sediments, *Activated sludge, Sludge, *Wastewater, Pollutant identification.

This paper describes an adaptation of the sedimentation technique of Sharp, performed so that total numbers of bacteriophages in samples from complex aqueous systems such as sewage, activated sludge mixed liquor, and bovine rumen fluid can be quantitated. All samples of sewage and activated sludge mixed liquor were obtained from Unit 1 of the Limestone Creek treatment plant at Gaffney, South Carolina. Sewage entering the plant was solely from domestic sources. Conditions for sample clarification, phage recognition, and recovery were optimized. In contrast to the plaque assay, this procedure permits quantitation of total numbers of phages, independent of bacterial host. Also, the modifications increase the sensitivity of the sedimentation assay, permitting detection of particles at a minimum concentration of 10,000 per ml. Maximal total phage concentrations in the aqueous phase of sewage and activated sludge mixed liquor were 1,300,000 and 4,300,000 per ml, respectively. This assay is the first one adapted for direct enumeration of total bacteriophages suspended in samples of unpurified aqueous ecosystems. (Baker-FRC)

AUTOMATION OF WATER BACTERIOLOGICAL ANALYSIS: RUNNING TEST OF AN EXPERIMENTAL PROTOTYPE,
Lille-1 Univ., Villeneuve d'Ascq (France).
P. A. Trinel, N. Hanoune, and H. Leclerc.
Applied and Environmental Microbiology, Vol 39, No 5, p 976-982, May, 1980. 6 Fig, 2 Tab, 9 Ref.

Descriptors: *Water quality, *Measuring instruments, Monitoring, Drinking water, Potable water, *Bacterial analysis.

An experimental apparatus is described which allows continuous and automatic bacteriological water examination. The apparatus ensures the analysis and detection of Escherichia coli by incubation of the water samples and then detection of glutamic acid decarboxylase in coils according to the Technicon principle. The analysis itself is rapid, taking less than 13 hr with a sensitivity of better than 1 bacterium/100 ml. A group of 120 samples of 100 ml of water can be examined in 24 hr. The device proved to be about as sensitive as conventional methods, with the observed differences arising from the low bacterial concentrations of the tested samples. The incubation coil made of Rilsan tubing ensured better flow stability than the usual glass coils and also permitted the removal of a great number of nipples, which could have been a possible source of contamination. Each week the culture coil should be cleaned with a sodium hypochlorite solution. Every three weeks the pump tubes should be replaced. Every month the ultrafiltration fibers should be changed. The phthalate-hydrochloric acid buffer decontamination method has proven to be very effective, always ensuring perfect integrity of the samples. The automatic device has the advantage of giving a much more representative sampling than is customarily obtained. The method costs about 75 cents per sample to run and allows rapid control of the treatment quality of water, as the analysis is carried out immediately in the treatment station. (Baker-FRC)

DETERMINATION OF AMINOCARB IN WATER BY HIGH PERFORMANCE LIQUID CHROMATOGRAPHY,
Department of the Environment, Moncton (New Brunswick). Inland Waters Directorate.
G. L. Brun, and R. M. MacDonald.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 6, p 886-893, 1980. 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Aminocarb, *Pesticide residues, *Water analysis, Pollutant identification, Carbamate pesticides, Insecticides, *Gas liquid chromatography.

Residues of aminocarb (4-dimethylamino-3-methylphenyl N-methylcarbamate) in water were determined by reverse phase high performance liquid chromatography using ultraviolet absorbance (254 nm) with fluorescence detection (248 nm). The water samples were preconcentrated by pouring through Amberlite XAD-4 resin and eluting with ethyl acetate. After drying, the extract was concentrated to 5-10 ml and the solvent replaced with acetonitrile. In addition to aminocarb, some degradation products (carbamates and phenols) were included in the study to determine the feasibility of their identification and the degree of interference. Details on the overlapping and detection are discussed. Recoveries were 76% as determined with spiked lake water samples. Using a signal to noise ratio of 2:1, detection limits were 0.5 micrograms per liter and 0.05 micrograms per liter for UV absorption and fluorescence detection, respectively. Rain water samples analyzed by this method and by gas-liquid chromatography were in good agreement; samples contained from about 0.15 to 5 micrograms per liter aminocarb. Other carbamates which did not interfere with the analysis were propoxur, carbofuran, carbaryl, methiocarb, and mexacarbate. (Cassar-FRC)

TRACE METAL GEOCHEMISTRY IN SEDIMENTS FROM THE MIRAMICHI ESTUARY, NEW BRUNSWICK,
North Carolina Univ. at Wilmington. Department of Chemistry.
J. D. Willey, and R. A. Fitzgerald.
Canadian Journal of Earth Sciences, Vol 17, No 2, p 254-265, 1980. 5 Fig, 6 Tab, 27 Ref.

Descriptors: *Estuarine environment, *Trace elements, Manganese, Zinc, Lead, Copper, Minerals, Mine wastes, Urban drainage, Industrial wastes, Miramichi Estuary, New Brunswick, Canada, Trace metals, Bottom sediments.

Forty-six sediment samples were collected in May of 1976 from the Miramichi estuary. Three core samples were obtained from the river and estuary and three vibrocores from the estuary and Inner Bay in February of 1977. Concentrations of lignin-rich organic matter, up to 10% of the total sediment weight in the central estuary, correlated with analytical results for trace elements, which showed that more than 40% of the total Mn, Zn, and Cu is held in the oxidizable and organically-bound state. Mineralogical influences were most obvious in the river portion, where Mn concentrations averaged 695 micrograms/g, zinc averaged 282 micrograms/g, copper averaged 32 micrograms/g, and lead averaged 200 micrograms/g in the less than 63 micrometer size fraction of the sediments. Concentrations of all trace elements in the coarse fraction were considerably less as compared with the fine fraction. Very high organic carbon content was associated with sediments in which more than 25% of the Mn, Zn, and Cu was organically bound. When compared with sediments from other eastern Canada areas, the Miramichi sediments have at least twice the weak acid leachable Zn; this higher level of reactive metal is associated with high organic carbon content in the top 15 cm of the cored sediments. Suggested sources include mining activities as well as urban and industrial effluents. (Baker-FRC)

A SALICYLATE-HYPOCHLORITE METHOD FOR DETERMINING AMMONIA IN SEAWATER,
Sea Research Foundation, West Hartford, CT. Inst. for Aquarium Studies.
C. E. Bower, and T. Holm-Hansen.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 5, p 794-798, May, 1980. 3 Tab, 24 Ref.

Descriptors: *Ammonia, *Seawater, *Marine animals, Nitrogen compounds, Cultures, *Pollutant identification, Water analysis.

Total ammonia-N at levels of 10 to 1000 micrograms per liter in artificial seawater was determined by reaction of ammonia with sodium salicylate-sodium nitroprusside catalyst solution and sodium hypochlorite to produce indophenol blue. Absorbances were measured by spectrophotometer at 640 mm. The salicylate-hypochlorite method and the phenol-hypochlorite method showed excellent agreement at levels of 10 to 500 micrograms per liter of ammonia-N. Coefficients of variation for samples containing 25 or more micrograms per liter of ammonia-N were less than 3% for the salicylate method. Since sodium salicylate is light sensitive and samples should be read within three hours, the method may not be suitable for field use. The characteristic color produced by the reagent permits visual estimates of the ammonia levels in culture systems. Zero level ammonia produces a light yellow; 100 micrograms per liter, green; and 1000 micrograms per liter, blue, with gradations of color between. (Cassar-FRC)

ISOLATION OF METHANOBACTERIUM BRYANTII FROM A DEEP AQUIFER BY USING A NOVEL BROTH-ANTIBIOTIC DISK METHOD,

Geological Survey, Menlo Park, CA. Water Resources Div.
E. M. Godsy.
Applied and Environmental Microbiology, Vol 39, No 5, p 1074-1075, May, 1980. 13 Ref.

Descriptors: *Bacteria, *Aquifers, Methanogenesis, Measuring instruments, Cultures, Water treatment facilities, Wastewater treatment, Wells, Pollutant identification.

A method for the isolation of a methanogenic bacterium from a mixed culture using a complex growth medium supplemented with antibiotic susceptibility disks is presented. The disk medium was prepared by adding from one to five antibiotic susceptibility disks to tubes of sterile broth medium in serum tubes capped with black rubber stoppers and crimped with aluminum seals. Tubes of sterile broth medium were inoculated with water samples obtained from wells located on the grounds of the West Palm Beach Regional Water Pollution Control Plant. The wells extended 657 to 673 meters below the land surface and flowed freely under an artesian head. After inoculation, the gas phase in each tube was exchanged for a pressurized atmosphere of 80% hydrogen and 20% carbon dioxide. The tubes were incubated at 30 degrees C for 4 weeks. The presence of methane in the headspace was monitored periodically by a gas chromatograph fitted with thermal conductivity detectors and a Poropak Q column. Total methane production in the headspace after 3 days averaged 1.2 micromol in all tubes except those containing chloramphenicol. No methane or cellular growth was noted in chloramphenicol containing medium after 21 days. Total methane production in the headspace averaged 76 micromol in all growth-supporting media after 7 days of growth. After antibiotic treatment, enrichment of fluorescent bacteria was noted in all media, but only in the presence of cephalothin (6-30 micrograms/ml) and clindamycin (1.6 and 2.0 micrograms/ml) was it noted that the cultures contained only fluorescing cells. The broth-antibiotic disk method offers a means by which methanogenic bacteria can be easily isolated from mixed cultures of bacteria. (Baker-FRC)

CONCENTRATION OF POLIOVIRUS IN WATER BY MOLECULAR FILTRATION,
Environmental Monitoring and Support Lab., Cincinnati, OH.
D. Berman, M-E. Rohr, and R. S. Safferman.
Applied and Environmental Microbiology, Vol 40, No 2, p 426-428, August, 1980. 3 Tab, 11 Ref.

Descriptors: *Viruses, *Filtration, Water quality, Water treatment, *Wastewater treatment, Poliovirus.

The efficiency of concentrating poliovirus 1 from distilled water samples was determined by using a recirculating-flow molecular filtration system. The molecular filtration unit was equipped with two PT series membranes which had a total surface area of 920 square centimeters and a nominal molecular weight limit of either 10,000 or 100,000. Two of the four ports connected to the manifold of the unit served as filtrate outlets. The sample-retentate flow, to and from the unit, was through the remaining two ports. Virus feed samples at a final concentration of 1 to 10 plaque-forming units per ml were prepared by rapidly mixing poliovirus 1 (Mahoney LP) in 2- or 4-liter volumes of distilled water. Initially, membranes with a 100,000 nominal molecular weight limit were used. Virus recoveries in this system after 23- to 46-fold concentrations averaged only 10.5%, and less than 1% of the unaccounted-for virus was present in the filtrate. To check the possibility that virus was nonreversibly adsorbed on the membranes, single runs were made in which 1% glycine was used either to pretreat the membrane or to supplement the feed. Either treatment resulted in the apparent blockage of virus adsorption sites. When these treatments were combined, the average recovery of virus increased to 39.0%. Upon pretreatment with flocculated beef extract, a nearly five fold increase in virus recovery was noted. At the same time the number of virions passing into the filtrate averaged 20.4% of the total viral input. The results of the study indicate that the described molecular filtration system can effectively concentrate viruses from water, provided membranes are pretreated with flocculated beef extract. Clarification may be needed for water containing suspended particles larger than 10 micrometers. (Baker-FRC)

CONCENTRATION OF COLIPHAGES FROM LARGE VOLUMES OF WATER AND WASTEWATER,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
S. M. Goyal, K. S. Zerda, and C. P. Gerba.
Applied and Environmental Microbiology, Vol 39, No 1, p 85-91, January, 1980. 10 Tab, 35 Ref.

Descriptors: *Bacteria, *Filters, Drinking water, Wastewater, Measuring instruments, Secondary treatment, Natural waters, Water quality, Coliphages.

An evaluation was made of the positively charged filters used for concentrating coliphages from sewage and tap water, and they were compared with negatively charged filters. Four different coliphages were studied. Positively charged microporous filters were found to efficiently adsorb these coliphages from tap water, sewage, and lake water at neutral pH. Adsorbed viruses were eluted with a 1:1 mixture of 8% beef extract and 1 M sodium chloride at pH 9. Using this method, coliphages could be concentrated from 17-liter volumes of tap water with recoveries ranging from 34 to 100%. Coliphages occurring naturally in raw and secondarily treated sewage were recovered with average efficiencies of 56.5 and 55.0%, respectively. This method should be useful in isolating rare phages, studying the ecology of phages in natural waters, and evaluating water quality. (Baker-FRC)

TEMPORAL VARIATIONS IN TRIHALOMETHANE CONTENT OF DRINKING WATER,
Texas Univ. Health Science Center, Houston. Dept. of Environmental Sciences.
V. L. Smith, I. Cech, J. H. Brown, and G. F. Bogdan.
Environmental Science and Technology, Vol 14, No 2, p 190-196, February, 1980. 8 Fig, 1 Tab, 14 Ref.

Descriptors: *Drinking water, *Organic compounds, *Trihalomethanes, Chemical analysis, Water analysis, Timing, Variability.

The importance of temporal and spatial aspects in environmental monitoring of drinking water is stressed. Trihalomethane concentrations were measured every 4 hours for 7 days at a site within the University of Texas Health Science Center. This site is representative of a moderate size office building housing a population of about 750 persons during working hours and minimally staffed at night. The 24-hr variations in concentrations of total trihalomethanes, chloroform, dichlorobromomethane, dibromochloromethane and bromoform in drinking water were assessed in a dynamic system using a solvent-extraction electron-capture gas chromatographic procedure. Spectral analysis and replicate harmonic regression were used to evaluate temporal patterns in fluctuations of the trihalomethanes. Data indicate that for reliable monitoring the time of sampling is an important factor. Both within the 24 hr period and in day to day samples, variations in the results were clearly evident. Naturally, these findings have a bearing on the predictability of trihalomethane concentrations in drinking water. (Baker-FRC)

IDENTIFICATION OF ORGANIC COMPOUNDS IN A MUTAGENIC EXTRACT OF A SURFACE DRINKING WATER BY A COMPUTERIZED GAS CHROMATOGRAPHY/MASS SPECTROMETRY SYSTEM (GC/MS/COM),
Health Effects Research Lab., Cincinnati, OH.
W. E. Coleman, R. G. Melton, F. C. Kopfler, K. A. Barone, and T. A. Aurand.
Environmental Science and Technology, Vol 14, No 5, p 576-588, May, 1980. 3 Fig, 1 Tab, 34 Ref.

Descriptors: *Organic compounds, *Trace levels, *Water analysis, *Drinking water, Mutagenesis, Gas chromatography, Polychlorinated biphenyls, Aromatic compounds, Amines, Chlorinated hydrocarbons, Pollutant identification, Reverse osmosis, Mass spectrometry.

Reverse osmosis and lyophilization were used to concentrate organic compounds from drinking water in Cincinnati, Ohio. The diethyl ether soluble extract of this concentrate, which was mutagenic according to the Ames test, was partitioned into acid and base/neutral fractions. Computerized gas chromatography/mass spectrometry was used to analyze the following: original concentrate, acid fraction, methylated acid fraction, unpartitioned base/neutral extract, and 5 base/neutral eluants from silica gel partitioning. Polychlorinated biphenyls (PCB) and chlorinated aromatics were found in the second base/neutral fraction, and polynuclear aromatic hydrocarbons in the fourth base/neutral fraction. Altogether, 460 organic compounds were identified: 41 polynuclear aromatics, 15 PCBs, ketones and aldehydes (C3 to C20), alcohols (C3 to C19), ethers (C3 to C12), acids (C2 to C20), esters and lactones (C2 to C26), nonaromatic hydrocarbons (C2 to C26), phthalates and anhydrides (C8 to C28), and compounds containing halogens, sulfur, phosphorus, and nitrogen. GAS CHROMATOGRAPHIC DETERMINATION OF SELENIUM (-II, O), -(IV), AND -(VI) IN NATURAL WATERS,
Okayama Univ. (Japan). Dept. of Chemistry.
H. Uchida, Y. Shimoishi, and K. Toei.
Environmental Science and Technology, Vol 14, No 5, p 541-544, May, 1980. 6 Fig, 4 Tab, 6 Ref.

Descriptors: *Selenium, *Water analysis, *Metals, Pollutant identification, *Gas chromatography, Natural waters, Seawater, Trace metals.

Selenium in river water and seawater was determined by electron capture detection gas chromatography using 1,2-diamino-3,5-dibromobenzene. This reagent reacts only with Se(4+) to form 4,6-dibromopiazselenol, which is extracted into toluene and determined by gas chromatography. Se(2-) and Se(0) are oxidized by Br to Se(4+); Se(6+) is reduced by a bromine-bromide solution to Se(4+). The Se(4+) is detected, and the amounts of Se in different oxidation states calculated by difference. The lower limit of the method is 2 ng per liter. The seawater samples tested contained 50-70 ng per liter Se, and river water, 16-230 ng per liter. River water contains more Se(2-) and Se(0) and less Se(6+) than seawater. (Cassar-FRC)
W82-00257

DETERMINATION OF ORGANICALLY COMBINED CHLORINE IN HIGH MOLECULAR WEIGHT AQUATIC ORGANICS,
Minnesota Univ., Minneapolis. Dept. of Chemistry.
M. P. McCahill, L. E. Conroy, and W. J. Maier.
Environmental Science and Technology, Vol 14, No 2, p 201-203, February, 1980. 5 Tab, 10 Ref.

Descriptors: *Chlorine, *Water analysis, Chemical analysis, Organic compounds, *Chlorination, Disinfection, Water treatment.

A method to determine total organic chlorine content of high molecular weight aqueous organic mixtures by photochemical mineralization was developed. In chlorinated sewage effluent total organic chlorine was found to increase after chlorination, so that from 0.002 to 0.009 ml of total organic chlorine per mol of total organic carbon

was present. Thus, chlorination of sewage effluents was shown to produce small amounts of organochlorine compounds of molecular weight greater than 1000 as defined by ultrafiltration of the sample. In its present form, this method is not sufficiently sensitive to detect total organic chlorine in unpolluted waters. However, sensitivity can be increased in principle to any desired level by more extensive preconcentration of the sample. In this method total organic chlorine is measured after preconcentrating the sample, photolyzing the organics to mineralize the chlorine, and measuring inorganic chloride. (Baker-FRC)
W82-00258

CONCENTRATION OF SEEDED SIMIAN ROTAVIRUS SA-11 FROM POTABLE WATERS BY USING TALC-CELITE LAYERS AND HYDROEXTRACTION,
Ottawa Univ. (Ontario). Dept. of Microbiology and Immunology.
S. Ramia, and S. A. Sattar.
Applied and Environmental Microbiology, Vol 39, No 3, p 493-499, March, 1980. 6 Tab, 38 Ref.

Descriptors: *Drinking water, *Water pollution control, Monitoring, Rotavirus, Viruses, Human diseases, *Pollutant identification, Tal-Celite adsorption, Polyethylene glycol.

The combined use of talc-Celite adsorption and polyethylene glycol 6000 hydroextraction was tested for its efficiency in preparing water samples to analyze for possible rotavirus contamination. The water to be sampled was seeded with simian rotavirus SA-11 and MA-104 cells. The dechlorinated tap water samples were adjusted to pH 6.0, and addition of Earle balanced salt solution was made to a final concentration of 1:100. Passage of a one liter volume of such a sample through a layer containing a mixture of talc (300 mg) and Celite 503 (100 mg) led to the adsorption of nearly 93% of the added SA-11 plaque-forming units. For the recovery of the layer-adsorbed virus, 3% beef extract and lx tryptose phosphate broth were found to be superior to a variety of other eluents tested. When the 100 liter sample volumes were tested, layers containing 1.2 g talc and 0.4 g Celite were used. Virus elution was conducted with 100 ml of tryptose phosphate broth. The eluate was concentrated 10-fold by overnight hydroextraction at 4 degrees C with polyethylene glycol. With total virus inputs of 7.0 x 10 to the fifth power and 1.4 x 10 to the second power plaque-forming units, the recoveries were about 71% and 59%, respectively. The use of this combination of techniques may be of use to detect the presence of rotavirus contamination in drinking water, and thus may be helpful in controlling outbreaks of rotavirus gastroenteritis. (Baker-FRC)

EVALUATION OF METHODOLOGIES FOR THE DETERMINATION OF ACUTE TOXICITY IN PULP AND PAPER EFFLUENTS,
Institute of Paper Chemistry, Appleton, WI.
E. F. Zanella, and S. A. Berben.
Tappi, Vol 63, No 3, p 77-82, March, 1980. 1 Fig, 6 Tab, 21 Ref.

Descriptors: *Bioassay, *Fish, *Pulp and paper industry, Pollutant identification, Water pollution effects, Toxicity, Fathead minnows, Daphnia, Caddisflies, Larvae, Testing procedures, Pulp wastes, Effluents, Industrial wastes, Sulfites.

Acute toxicity bioassays for pulp and paper mill effluents were evaluated in a multiple-parameter testing program using treated and untreated samples of unbleached kraft, bleached sulfite, and bleached kraft mill effluent. Test organisms included fathead minnows (Pimephales promelas), Daphnia (Daphnia magna), and caddis fly larvae (Hydropsyche sp.). There was no appreciable difference in the LC50 values from the following fish tests: dynamic, 24-hour replacement, and static bioassays. The 12-hour replacement fish bioassay gave comparable results but was more variable. The residual oxygen assays did not coincide with LC50 values from standard tests and failed to produce a response to several of the toxic effluents tested. The relative sensitivity of Daphnia, caddis fly larvae, and fathead minnows was consistent for different samples of the same effluent type but different for different effluents. Daphnia were sensitive to bleached sulfite effluents but resistant to bleached kraft mill effluent. Caddis fly larvae was the least sensitive of the test organisms used. (Cassar-FRC)

DISTRIBUTION OF OBLIGATELY OLIGOTROPHIC BACTERIA IN LAKE BIWA,
Kyoto Univ. (Japan). Dept. of Fisheries.
Y. Ishida, K. Shibahara, H. Uchida, and H. Kadota.
Bulletin of the Japanese Society of Scientific Fisheries, Vol 46, No 9, p 1151-1158, 1980. 7 Fig, 2 Tab, 14 Ref.

Descriptors: *Oligotrophy, *Bacteria, *Aquatic microorganisms, *Lake Biwa, Japan, Lakes, Epilimnion, Hypolimnion, Bioindicators, Water pollution effects.

The NPN-C14-substrate method was used to investigate seasonal changes and vertical and horizontal distributions of oligotrophic bacteria in Lake Biwa, Japan. In unpolluted areas the ratio of obligate oligotrophic bacteria to total heterotrophic bacteria was 50%, and in moderately polluted waters 15%, while in heavily polluted waters none were detected. The vertical distribution was studied in unpolluted waters. At the thermocline the ratio of total oligotrophs to total heterotrophs was lowest, and eutrophs were predominant. In the epilimnion, proportions were very variable; there was less variability in the hypolimnion. During three periods of algal bloom no obligate oligotrophs were detected in the water. There were large populations present in unpolluted water from late May to early autumn. (Cassar-FRC)

DISTRIBUTION OF CLOSTRIDIUM BOTULINUM,
Technical Univ. of Denmark, Lyngby. Technical Lab.
H. H. Huss.
Applied and Environmental Microbiology, Vol 39, No 4, p 764-769, April, 1980. 3 Tab, 31 Ref.

Descriptors: *Clostridium botulinum, *Distribution patterns, *Aquatic environment, *Bacteria, Soil bacteria, Aquatic bacteria, Microbiological studies, Sediments.

The incidence and distribution of C. botulinum in the soil, freshwater sediments, and marine environments of Denmark, the Faroe Islands, Iceland, Greenland, and Bangladesh were determined. Six hundred eighty-four samples were tested. Type E was found in 90% of the Danish aquatic samples and in 86% of the marine samples from Greenland. Type E was not present in Danish cultivated soils and woodland soils, but Type B was frequently found in these environments. Types A, B, or E were present in 2.6% of the samples collected in the Faroe Islands and Iceland, and Types C and D were found in 42% of the Bangladesh samples. Neither general industrial pollution nor a high rate of rotting vegetation was related to the incidence of Type E. Presence of fish or a rich aquatic fauna did appear to be related to a high incidence of Type E. Type E may be a true aquatic organism, because its environment offered the best conditions for spore survival. (Small-FRC)

ANALYTICAL METHODS EVALUATION FOR APPLICABILITY IN LEACHATE ANALYSIS,
Washington Univ., Seattle.
F. B. DeWalle, T. Zeisig, J. F. C. Sung, D. M. Norman, and J. B. Hatlen.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-172306, Price codes: A15 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-046, May 1981. 4 p, 3 Tab.

Descriptors: *Leachates, *Pollutants, *Water analysis, Physical properties, Chemical properties, Organic compounds, Cations, Anions, Variation coefficient, Statistical analysis, Precision, *Pollutant identification.

Thirty-two laboratories in the United States and Canada conducted round-robin analyses of leachate samples. Ten samples from nine locations and one spiked sample were analyzed for up to 28 parameters to evaluate accuracy and precision of the methods employed. The 28 parameters included physical parameters (pH, oxidation reduction potential, conductivity, turbidity, and solids), organics (chemical oxygen demand, total organic carbon, organic nitrogen, and free volatile fatty acids), anions (sulfate, phosphate, chloride, nitrate, and bicarbonate), and cations (alkali metals, alkaline earth metals, transition metals, and heavy metals). Individual parameter coefficients of variation ranged from 32% for COD to 210% for cadmium. Significant differences were noted between results from colorimetric methods and from titrimetric and physical methods. The between-laboratory component of variation was larger than the within-laboratory component. The average recovery for spiked parameters varied widely for individual parameters. The most applicable method for analysis of each parameter is recommended. Use of the standard addition technique is required in each laboratory to determine the matrix depression or enhancement for each type of leachate sample. The accuracy (agreement between measured and actual amounts) and the precision (reproducibility) of different analytical methods were evaluated in depth. (Brambley-SRC)

METHODS FOR LEVEL 2 ANALYSIS BY ORGANIC COMPOUND CATEGORY,
Little (Arthur D.), Cambridge, MA.
K. E. Thrun, J. C. Harris, C. E. Rechsteiner, and D. J. Sorlin.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-179855, Price codes: A14 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-029, July 1981. 3 p, 3 Ref.

Descriptors: *Effluents, *Industrial wastes, *Organic compounds, *Chemical analysis, Gas chromatography, Mass spectrometry, Pollutants, Environmental effects.

As a step in the development of a general methodology for chemical and biological assessment of environmental effects of industrial effluents, specific detailed methods for analysis of organic chemicals in particular compound categories were evaluated. This supplements the earlier Level 2 Procedures manual and provides an initial experimental data base as a resource for laboratories undertaking Level 2 studies. Methods were evaluated using sets of model compounds spanning a range of molecular weights and boiling points in each category. Evaluation criteria included: detection limit, retention time, chromatographic resolution, and precision and accuracy of the methods. Specific detailed Level 2 methods have been recommended for 25 categories of organic compounds. Most of the primary recommendations are based on packed column gas chromatography/mass spectrometry, with alternative procedures suggested where appropriate for particular sample matrices or compound types. Level 2 inquiries are expected to be directed primarily at the identification quantification, and confirmation of specific compounds whose presence could be inferred on the basis of the categorical analysis of Level 1. THE ANALYSIS OF OIL SHALE WASTES: A REVIEW,
Denver Univ., CO. Charles H. Prien Center for Synthetic Fuel Studies.
J. R. Wallace.

Available from the National Technical Information Service, Springfield, VA 22161 as PB81-190522, Price codes: A13 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-084, July 1981. 4 p, 1 Tab.

Descriptors: *Oil shale, *Industrial wastewater, *Chemical analysis, *Wastewater analysis, Hydrogen ion concentration, Conductivity, Ammonia, Ammonium, Sulfur compounds, Organic compounds, Dissolved solids.

The current status of methods for chemical analysis of oil shale effluents was studied in order to provide a reference for those who must measure and control the effects of oil shale waste products on the environment. The effluents studied include spent and raw shale, process waters of various types, retort gas and burned fuel gas. Methods were considered for the measurement of trace and minor elements, dissolved ions, organic compounds, sulfur and nitrogen species of environmental importance, and physical properties such as dissolved solids. When analytical methods developed for simple, homogeneous material are applied to complex samples like oil shaleeffluents, extraordinary interferences or matrix effects can render the method ineffective. Methods for determining pH, conductivity, fluorine, ammonium and ammonia have been shown to be adequate for a limited number of wastewaters. Methods for other dissolved inorganics such as chloride, phosphate, total phosphorus, and sulfur oxides either lack confirmation or have been shown to be inaccurate. Quality assurance is of utmost importance when dealing with analytical methods for the chemical determination of oil shale samples. (Moore-SRC)

A BACTERIAL BIOASSAY FOR ASSESSMENT OF WASTEWATER TOXICITY,
Oregon State Univ., Corvallis. Dept. of Civil Engineering.
K. J. Williamson, and D. G. Johnson.
Water Research, Vol 15, No 3, p 383-390, March, 1981. 8 Fig, 24 Ref. OWRT-A-036-ORE(2), 14-34-0001-6038.

Descriptors: *Bioassay, *Bacteria, Toxicity, Nitrogen fixing bacteria, Microorganisms, Nitrification, Wastewater analysis, Biological properties, Pollutant identification.

A bioassay technique using freeze-dried Nitrobacter as the test organism was applied to the analysis of a wastewater treatment system at a fiberboard plant near Portland, Oregon. Treatment facilities on site consist of settling ponds, activated sludge basin, clarifier and holding ponds. The treated water is recycled to the mill for reuse. Soluble and particulate organics began accumulating in the system when the removal of BOD dropped significantly. Both the influent and effluent flows were determined by this method to be toxic. This toxicity spread throughout the entire wastewater treatment system. Toxicity tests were conducted, but no single agent could be identified as the cause of the problem. Various physical and chemical methods were used to treat the situation. It was concluded that the Nitrobacter bioassay meets criteria for a bioassay of industrial and municipal wastewater and is simple and inexpensive for environmental source sampling. The bioassay is a sensitive indicator of toxicity in biological wastewater treatment and can be used to identify toxic wastewater sources and to evaluate treatment and control technologies. Applied Spectroscopy, Vol 34, No 1, p 72-75, January/February, 1980. 4 Fig, 3 Tab, 24 Ref. OWRT-B-078-RI(2).

Descriptors: *Water analysis, *Bacteria, Water quality control, Resonance, *Spectroscopy, Raman spectroscopy, Pollutant identification.

This study demonstrates that a substantial number of carotene-containing bacteria and algae produce specific, interpretable resonance Raman spectra when irradiated at 488.0 and 514.5 nm. Further, these spectra are easily obtained using simple sample preparation techniques. Spectra are of high quality and are reproducible. Such spectra may be suitable for rapid identification of bacteria even in the presence of substantial amounts of organic material. A total of 16 types of carotene-containing bacteria and algae were studied. Most of the information was contained in the 900 to 1600/cm region. Several bacteria exhibited pronounced carotenoid overtone and combination bands which could be assigned along with the fundamental vibrations. (Baker-FRC)

RADIONUCLIDE CONCENTRATIONS IN STREAMS IN THE UPPER BLACKFOOT RIVER BASIN, SOUTHEASTERN IDAHO,
Geological Survey, Boise, ID. Water Resources Div.
W. H. Low.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $4.00 in paper copy, $4.00 in microfiche. Geological Survey Open-File Report 81-142 (WRI), March 1981. 17 p, 2 Fig, 1 Plate, 4 Tab, 15 Ref.

Descriptors: *Surface water, *Water quality, *Pollutant identification, *Mine drainage, Streams, Overburden, Bottom sediments, Suspended sediments, Phosphates, Uranium, Sampling, Water analysis, Water quality standards, Geochemistry, Path of pollutants, *Idaho, Southeastern Idaho, Blackfoot River basin, Radium, *Phosphate mining, *Radionuclides.

Data on radionuclide concentrations in water and sediment material in the phosphate-mining area of the upper Blackfoot River basin were collected from May to October 1979. Maximum measured uranium and radium-226 concentrations dissolved in water were 3.7 micrograms per liter and 1.8 picocuries per liter, respectively. Maximum measured uranium and radium-226 concentrations in stream-bottom material were 5.5 micrograms per gram and 1.8 picocuries per gram, respectively. Maximum measured uranium and radium-226 concentrations on bottom material were 9.9 micrograms per gram and 3.9 picocuries per gram, respectively, in sediment-retention ponds, and 17 micrograms per gram and 3.5 picocuries per gram, respectively, in a mine pit. Maximum observed radon-222 concentration was 120 picocuries per liter in surface water and averaged 550 picocuries per liter at Formation Springs (site 10). All radionuclide concentrations were within existing State and Federal water-quality standards. Radionuclide concentrations were not significantly increased downstream from active mining sites. COMPARATIVE STUDY ON ORGANIC CONSTITUENTS IN POLLUTED AND UNPOLLUTED INLAND AQUATIC ENVIRONMENTS. II. FEATURES OF FATTY ACIDS FOR POLLUTED AND UNPOLLUTED WATERS,
Tokyo Metropolitan Univ. (Japan). Dept. of Chemistry.
G. Matsumoto.
Water Research, Vol 15, No 7, p 779-787, July, 1981. 2 Fig, 3 Tab, 25 Ref.

Descriptors: *Fatty acids, *Water analysis, Pollutant identification, Organic acids, Organic compounds, Natural waters, Rivers, Tokyo, Ogasawara Islands, Japan.

There was no marked difference between the fatty acid constituents of polluted rivers in the Tokyo area and unpolluted waters from the Ogasawara Islands. The predominant fatty acids in both types of water were even carbon chains in the lower molecular weight ranges, C13 to C19. Straight chain, unsaturated, and branched acids from C8 to C34 were detected. Tokyo waters contained total fatty acids at 270 + or - 120 micrograms per liter; fatty acids as carbon/total organic carbon, 2.6 + or - 0.93%; and fatty acids as carbon/ethyl acetate extractable organic carbon, 16 + or - 6.7%. Similar values for the Ogasawara Islands water were lower, 58 + or - 29 micrograms per liter, 0.79 + or - 0.48%; and 2.1 + or - 0.51%, respectively. Over 95% of the fatty acids were in particulate fractions. Levels of combined fatty acids were twice as great as those of free fatty acids. Unsaturated fatty acids were found only in the combined form. (Cassar-FRC)

APPLICATION OF A MULTIPLE ALGINATE FILTER METHOD FOR THE DETERMINATION OF WATER VIRUSES CONCENTRATION (CONCEPTION D'UNE MEMBRANE FILTRANTE A BASE D'ALGINATE POUR LA CONCENTRATION DES VIRUS HYDRIQUES),
Ecole Polytechnique, Limoges (France).
P. La France, A. J. Drapeau, and E. Kurstak.
Water Research, Vol 15, No 6, p 713-718, June, 1981. 2 Fig, 2 Tab, 16 Ref.

Descriptors: *Viruses, *Membrane filters, *Filtration, *Pollutant identification, Water treatment, Alginate filters, Water analysis, Gels.

Alginate gels were modified by additives to improve the filtration characteristics for concentrating viruses from large water samples. The filtering capacity of the pure 0.5% alginate unitary membranes increased directly with an increase in intramembrane concentrations of sodium gluconate. The filtration output of pure 0.75% alginate membranes remained constant for intramembrane Tween 80 concentrations of less than 0.5%. The existence of a stratified membrane (alginate-sodium gluconate and alginate-Tween 80) was recognized. The double membrane (sample volume, 5 liters) with or without 0.75% gluconate permitted no poliovirus to enter the filtrate. The unitary membranes (sample volume 10 liters), 0.5% and 0.75%, with and without sodium gluconate or Tween 80, had between 12.6% and 89.0% virus in the filtrate. (Cassar-FRC)

NITROSAMINES IN TAP WATER AFTER CONCENTRATION BY A CARBONACEOUS ADSORBENT,
Science and Education Administration, Philadelphia, PA. Eastern Regional Research Center.
W. I. Kimoto, C. J. Dooley, J. Carre, and W. Fiddler.
Water Research, Vol 15, No 9, p 1099-1106, September, 1981. 1 Fig, 7 Tab, 15 Ref.

Descriptors: *Nitrosamines, *Water analysis, *Carcinogens, Amines, Nitrogen compounds, *Drinking water, Adsorption, Ion exchange resins, Activated carbon, Pollutant identification.

Volatile nitrosamines were determined in municipal tap water using Ambersorb XE-340, a carbonaceous adsorbent. Between 58 and 99% of seven added nitrosamines were removed from spiked distilled water samples. Analysis of tap water (flow rate through the adsorbent, 1.2 liters per hour) showed the following levels of nitrosamines, in micrograms per liter: N-nitrosodimethylamine, 0.003-0.006; N-nitrosmorpholine, 0.006-0.016; and N-nitrosodiethylamine, traces. When low levels of secondary amines were added to tap water, nitrosamines were detected, indicating that the water had nitrosating ability. Experimental evidence obtained by adding sulfamic acid, piperidine, and sodium sulfite to the water showed that the nitrosamines did not form on the resin. It was proposed that the trace nitrosamines may have been produced from the reaction of nitrates (present at levels up to 10 micrograms per liter N02-N) with an oxidizing agent, such as chlorine, and amines in the water. CLINICAL TESTS IN AQUATIC TOXICOLOGY: STATE OF THE ART,
Columbia National Fisheries Research Lab., MO.
P. M. Mehrle, and F. L. Mayer.
Environmental Health Perspectives, Vol 34, p 139-143, February 1980. 20 Ref.

Descriptors: *Aquatic life, *Toxicity, Chemical compounds, Water pollution, Assessment, Poisons, Indicators, Bioindicators, Public health, Environmental effects, Effects of pollutants, *Fish.

Problems involved in developing diagnostic tests for fish are described, along with the philosophy behind their development and their application in aquatic toxicology. Development of diagnostic tests for fish requires consideration of an understanding of the functions and composition of organs primarily affected by toxic chemmicals; knowledge of analytical procedures to measure appropriate biochemical constituents, cellular morphology, and physiological responses; and the ability to interpret the significance of chemical-induced biophysiological changes and relate them to fish health and survival. The current state of the art of clinical analyses or diagnostic tests in aquatic toxicology is not well advanced. Useful diagnostic or biological indicators have not been developed. One major problem has been the lack of a comprehensive, integrated approach in toxicological studies on fish. To adequately assess the influence of contaminants on the aquatic environment and to overcome the avoidance of biochemical and physiological testing, investigators should develop techniques that can serve as biological indicators in the field as well as predictors in the laboratory to estimate the health of a particular aquatic resource. One of the major principles to be followed is the need to plan and execute the biochemical and physiological research within the framework of conditions existing in the 'real world'. (Baker-FRC)

TADPOLES AS INDICATORS OF HARMFUL LEVELS OF POLLUTION IN THE FIELD,
Nature Conservancy, Abbotts Ripton (England). Monks Wood Experimental Station.
A. S. Cooke.
Environmental Pollution, (Series A), Vol 25, No 2, p 123-133, June, 1981. 4 Fig, 31 Ref.

Descriptors: *Frogs, *Bioindicators, *Water pollution effects, Indicators, *Tadpoles, Water pollution, Oxamyl, Sublethal effects, Runoff, Spraying.

A technique was developed using caged tadpoles to assess potential freshwater pollutants from runoff of spray drift. Mortality, growth, rate of metramorphosis, and occurrence of deformities are monitored. A field test was performed, and the incidence of tadpole deformities was found to be unusually high in cages near a potato field which was treated with oxamyl. Oxamyl is a carbamate nematicide and insecticide. Tadpoles next to the potato fields suffered significantly higher incidences of vertical curvature deformities. Treatment of tadpoles in the laboratory showed similar results. Thus, exposure to environmental stress can cause increases in deformities seen in tadpoles. While this does not prove that the chemical being tested is dangerous, it indicates that the chemical warrants further study. (Small-FRC)

CHARACTERIZATION OF SOLUBLE AND COLLOIDAL-PHASE METAL COMPLEXES IN RIVER WATER BY ULTRAFILTRATION. A MASS-BALANCE APPROACH,
Minnesota Univ., Minneapolis. Dept. of Civil and Mineral Engineering.
M. R. Hoffmann, E. C. Yost, S. J. Eisenreich, and W. J. Maier.
Environmental Science and Technology, Vol 15, No 6, p 655-661, June, 1981. 3 Fig, 3 Tab, 64 Ref.

Descriptors: *Ultrafiltration, *Trace metals, *Rivers, Measurement techniques, Membrane filters, Organic matter, Copper, Calcium, Magnesium, Colloids, Solutes, Cadmium, Lead, Dissolved solids, Molecular structure, Mathematical equations.

Previous water quality studies have indicated that it is necessary to know both the total metal concentrations in soluble and particulate phases and the species of the metal in order to reliably predict biological availability and ultimate fate in aquatic systems. This paper reports the development of a new approach to size fractionation by ultrafiltration which uses a cascade procedure and a system of mass-balance equations, eliminating the need for repeated washings or excessive concentration. This procedure is followed by atomic absorption spectrophotometry and anodic stripping voltammetry measurements of metal concentrations. The process has been used to determine the distribution and degree of association of major trace metals with discrete size fractions of dissolved organic matter which initially passes through a 0.4 micrometer membrane filter. Application of the process to samples from the Mississippi and Minnesota Rivers demonstrated that the highest concentrations of trace metals are often found in intermediate molecular weight ranges (1,000 to 10,000) with no detectable free or labile metal as determined by anodic stripping voltammetry. Calcium and magnesium, which were generally found in the lower molecular size ranges, did not appear to have a significant impact on the apparent extent of interaction of other metals with dissolved organic matter. The moderate residual complexation capacity for copper (1.0 plus or minus 0.1 microM) and the relatively high pseudostability constant (log K = 10.4) for copper complexation found in samples from the Mississippi River suggest that complexation of trace metals such as copper, cadmium, and lead may be dominated by aquatic organics and that formation of carbonato complexes is of secondary importance. COMPARISON OF AUTOMATED SEGMENTED-FLOW AND DISCRETE ANALYZERS FOR THE DETERMINATION OF NUTRIENTS IN WATER,
National Water Quality Lab., Arvada, CO.
V. C. Marti, and D. R. Hale.
Environmental Science and Technology, Vol 15, No 6, p 711-713, June, 1981. 4 Fig, 2 Tab, 5 Ref.

Descriptors: *Nutrients, *Water analysis, *Measurement techniques, Chemical analysis, *Colorimetry, Measuring instruments, Comparison studies, Pollutant identification.

Many automated colorimetric analysis methods using segmented flow systems have come to be referenced as standard techniques. However, colorimetric analyses can usually be made with greater speed on automated 'discrete' systems for most of the chemical species determined by the referenced methods. The analytical results obtained using the Technicon AAII, a segmented flow system which automatically moves a sample through a closed system of tubing and mixing coils using air-segmented streams of reagents and sample, and the Coulter IKL, a discrete technique which automatically moves a sample and reagents in an open reaction tube through a water bath, were compared. Thirty-nine randomly selected water samples from six states were analyzed for ammonia-N (NH3-N), nitrate plus nitrite-N (NO3 plus NO2-N), nitrite-N (NO2-N), and phosphate-P (PO4-P). Plots of the discrete versus the segmented flow results demonstrated linear correlation coefficients of 0.9980 for NH3-N, 0.9997 for NO3 plus NO2-N, 0.9998 for NO2-N, and 0.9950 for PO4-P. The significances of the slope and of the y intercept of each plot are discussed in terms of possible biases which may exist between the two systems. The discrete analyzer was able to analyze 60 samples per hour for the four analytes, while the segmented-flow analyzer's rate was 40 samples per hour. The comparative accuracy and precision of the two instruments were indicated by the results of the standard reference analyses, by the results of six natural samples used for the precision study, and by the regression statistics pertaining to the 39 unknown water samples. MEMBRANE FILTER METHOD FOR ENUMERATING ESCHERICHIA COLI,
Health Effects Research Lab., West Kingston, RI.
A. P. Dufour, E. R. Strickland, and V. J. Cabelli.
Applied and Environmental Microbiology, Vol 41, No 5, p 1152-1158, May, 1981. 4 Fig, 3 Tab, 23 Ref.

Descriptors: *Membrane filters, *Escherichia coli, *Bacterial analysis, Coliforms, Bacteria, Enteric bacteria, Sewage bacteria.

Although many tests have been devised to enumerate Escherichia coli based on the ability of this organism to produce indole from tryptophane at an elevated temperature, there are two inherent problems with the method. The determination of indole production in conjunction with a most probable number procedure generally requires transfer of bacteria from lactose broth to another medium and an additional 24-hour incubation period. In addition, further examination of the colonies under consideration is prohibited since the reagents used for the indole test are bactericidal. The development of a simple, accurate, nonlethal membrane filter technique for rapid enumeration of E. coli is reported. E. coli can be quantitied within 24 hours using this method without requiring subculture and identification of isolates. The method incorporates a primary selective-differential medium for gram-negative, lactose-fermenting bacteria; resuscitation of weakened organisms by incubation for 2 hours at 35 degrees C prior to incubation at 44.5 degrees C for 18 to 22 hours; and an in situ urease test to differentiate E. coli from other thermotolerant, lactose-positive organisms. Use of the method on marine, estuarine, and freshwater samples resulted in recovery rates for E. coli exceeding 90%. Of the presumptively positive colonies, 91% were verified as E. coli. Nonspecificity occurred most often with fresh water samples, but the frequency of false-positive colonies (15%) was not high enough to preclude its use in those environments. Over 99% of the verified E. coli colonies reacted typically. (Carroll-FRC)

INCIDENCE OF VIBRIO ALGINOLYTICUS AND BACTERIA OF SANITARY SIGNIFICANCE IN THE BERING SEA,
Food and Drug Administration, Seattle, WA.
C. A. Kaysner.
Applied and Environmental Microbiology, Vol 41, No 5, p 1279-1282, May, 1981. 1 Fig, 2 Tab, 14 Ref.

Descriptors: *Sewage bacteria, *Bering Sea, *Vibrio, Bacteria, Marine bacteria, Marine environments, Sediments, Seawater, Clams, Mollusks, Environmental tracers, Commercial shellfishing, Public health.

Vibrio parahaemolyticus is a bacterium commonly isolated from temperate marine environments throughout the world. Vibrio alginolyticus, the non-enteropathogenic species, is commonly found in marine samples at temperatures above 5 degrees C. The feasibility of commercial clam harvest in the Bering Sea was studied by a joint industry-government assessment team in 1977. Clams, seawater samples, and sediment samples were analyzed in the bacteriological laboratory on board the National Oceanic and Atmospheric Administration's research vessel used in the study. The bacteriological counts of the clams, sediment samples, and seawater samples were all low. V. alginolyticus was isolated from 2 of 153 total samples at most probable numbers of 5.1 and 16 per 100 milliliters. V. parahaemolyticus was not detected in any of the samples, probably due to the low water temperatures. It is possible that V. parahaemolyticus may be found in the coastal regions of the Bering Sea, where temperatures are higher during the summer months. (Carroll-FRC)

MICROPLATE TECHNIQUE FOR DETERMINING ACCUMULATION OF METALS BY ALGAE,
Syracuse Univ., NY. Dept. of Civil Engineering.
J. M. Hassett, J. C. Jennett, and J. E. Smith.

Applied and Environmental Microbiology, Vol 41, No 5, p 1097-1106, May, 1981. 4 Fig, 6 Tab, 31 Ref.

Descriptors: *Heavy metals, *Algae, *Measurement techniques, Mercury, Lead, Cadmium, Zinc, Salinity, Bioaccumulation, Accumulation, Chelating agents, Pollutant identification.

Although the ability of many species of algae to accumulate metals from their aqueous environments may have a significant impact on bioaccumulation of metals in the food chain and implications for wastewater treatment, there has been no systematic survey of algae for this ability. A microplate analytic technique has been developed which can be used to determine the uptake of heavy metals by pure cultures of algae. The equipment includes plastic, U-bottomed microtiter plates, disposable harvesting frames, a transfer fork, and a press. The technique was used to survey the effects of several combinations of environmental factors on the removal of mercury, lead, cadmium, and zinc by green and blue-green algae and to describe the kinetics of metal uptake. Variables investigated included algal species and strain, culture age (11 and 44 days), pH, effects of different buffer solutions, and time of exposure. Concentration factors, which are the ratio of the metal concentration in the algae to that in the surrounding water, were determined for the various metal-alga combinations. The concentration factors obtained were in reasonably good agreement with those reported in the literature. Mercury was removed from solution by all species of algae studied, while no alga studied removed zinc, possibly due to keeping the cells in the dark during the labeling period. Green algae were found to be better at accumulating cadmium than were blue-green algae. Chlamydomonas sp. proved superior to all other species of algae studied in ability to remove lead from solution. The techniques was found to be rapid, statistically reliable, and economical of materials, cells, and laboratory space. There is no reason to believe that the technique could not be used successfully in similar studies with bacteria, fungi, protozoa, and other microbes or with other gamma-emitting and possibly beta-emitting nuclides. (Carroll-FRC)
W82-00492

IMPACT OF VERIFICATION MEDIA AND RESUSCITATION ON ACCURACY OF THE MEMBRANE FILTER TOTAL COLIFORM ENUMERATION TECHNIQUE,
Oregon State Univ., Corvallis. Dept. of Microbiology.
T. M. Evans, R. J. Seidler, and M. W. LeChevallier.
Applied and Environmental Microbiology, Vol 41, No 5, p 1144-1151, May, 1981. 2 Fig, 2 Tab, 23 Ref.

Descriptors: *Bacterial analysis, *Coliforms, *Membrane filters, Bacteria, Water quality, Filter media.

The membrane filter method is usually the method of choice for the enumeration of total coliforms in water supply samples. However, serious limitations of this technique have been discovered recently, including failure to detect coliforms in turbid drinking water samples and production of green sheen in lactose-containing media, which interferes with the accuracy of the count. A verification procedure has been adopted by the Environmental Protection Agency for use on green-sheen colonies. The influence of verification media and resuscitation on the number of membrane filter typical colonies which produce gas during verification was investigated. The use of lauryl tryptose broth (LTB), lactose broth (LB), and m-LAC broth as primary media was compared, and the need for and use of brilliant-green-lactose-bile (BGLB) broth as secondary media was investigated. Verification in m-LAC broth yielded the greatest number of aerogenic isolates for both untreated surface water and drinking water samples. Verification in BGLB broth increased the number of false-negative reactions. The addition of a resuscitation step in membrane filter analysis did not result in verification of greater numbers of coliforms per sample. The use of m-LAC broth for verification of typical and atypical colonies resulted in a 10-fold increase in coliform numbers from untreated surface water. Verification of both colony types in drinking water resulted in an increase from less than 1 coliform/100 milliliters to greater than 1/100 milliliters. It is concluded that a single-step verification in m-LAC broth would provide a more rapid and sensitive coliform verification procedure than the standard technique involving both subculturing in LTB and subsequent subculturing in BGLB broth. COMPARISON OF TWO DIRECT-COUNT METHODS FOR DETERMINING METABOLIZING BACTERIA IN FRESHWATER,
Wisconsin-Milwaukee Univ. Center for Great Lakes Studies.
J. S. Maki, and C. C. Remsen.
Applied and Environmental Microbiology, Vol 41, No 5, p 1132-1138, May, 1981. 1 Fig, 2 Tab, 29 Ref.

Descriptors: *Bacterial analysis, *Metabolism, *Aquatic bacteria, Bacteria, Freshwater, Analytical techniques, Comparison studies.

Since not all bacteria present in aquatic systems are metabolically active, determination of a normalized percentage of metabolically active cells to total counts would be useful to microbial ecologists interested in determining the influence of microorganisms on a given aquatic environment. Two methods for determining the numbers of metabolizing bacteria were compared using planktonic bacteria collected from several freshwater environments and cultured bacteria. The first method involves the reduction of 2-(rho-iodophenyl)-3-(rho-nitrophenyl)-5-phenyl tetrazolium chloride (INT) to INT-formazan crystals by active bacterial electron transport systems. The second method uses a preincubation of the sample with a combination of yeast extract and nalidixic acid (YE + NA), which results in specific inhibition of deoxyribonucleic acid synthesis and subsequent cell elongation. No statistically significant difference was found between methods in determining metabolizing bacteria, although significant differences ($P < 0.05$) were found when comparing numbers of total bacteria. The proportion of metabolizing bacteria with respect to the total count found in this study agreed with values previously reported. Combination of the two techniques resulted in slightly higher counts of metabolizing bacteria than those found in the tests performed individually in some cases and in significantly lower counts in several instances. Both methods are easily performed and provide data on total and metabolizing bacteria within a matter of hours. (Carroll-FRC)

MOUNT ST. HELENS VOLCANIC-ASH FALL IN THE BULL RUN WATERSHED, OREGON, MARCH-JUNE 1980,
Geological Survey, Portland, OR. Water Resources Div.
M. V. Shulters, and D. G. Clifton.
Available from the Br. of Dist., USGS, 604 S. Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-A, 1980. 15 p, 6 Fig, 3 Tab, 8 Ref.

Descriptors: *Volcanoes, *Environmental effects, *Water quality, Large watersheds, Water supply, Fallout, Particle size, Water pollution sources, Path of pollutants, Precipitation, Weather patterns, Oregon, *Bull Run watershed, Washington, *Mount St. Helens, *Volcanic ash.

During several periods of volcanic-ash eruption at Mount St. Helens, Wash., (March 30, May 25-26, May 30-June 2, and June 12-13, 1980) strong winds from the north occurred at high altitudes. As a result, the volcanic ash fell some 50 miles to the south in the Bull Run watershed, the principal water-supply source for the metropolitan area of Portland, Oreg. Water samples collected from three stream sites within the watershed were compared with samples collected during the same season in previous years. No detectable changes were noted in chemical characteristics. Precipitation samples collected immediately after the June 12-13 ash fall ranged in specific conductance from 20 to 41 micromhos per centimeter at 25C and in pH from 4.0 to 4.3 pH units. Stream samples collected during the May-June period ranged in specific conductance from 18 to 28 micromhos per centimeter at 25C and in pH from 6.7 to 7.5 pH units. Volcanic-ash samples were collected and analyzed for particle size, chemical composition, and weight. Significant differences in particle size of ash were found in samples from two separate eruptions. (USGS)

MUDFLOWS RESULTING FROM THE MAY 18, 1980, ERUPTION OF MOUNT ST. HELENS, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
J. Cummans.
Available from the Br. of Dist., USGS, 604 S. Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-B, 1981. 16 p, 11 Fig, 2 Tab, 2 Ref.

Descriptors: *Mudflows, *Volcanoes, *Streams, *Drainage areas, Avalanches, Detritus, Sediments, Floods, Runoff, *Washington, *Mount St. Helens, North Fork Toutle River, Toutle River, Cowlitz River, Debris avalanche, Volcanic ash.

On May 18, 1980, Mount St. Helens, in southwestern Washington, erupted violently, setting off a chain of devastating hydrologic event. During the eruption, a massive debris avalanche moving down the north side of Mount St. Helens was deposited in the North Fork Toutle River valley. Approximately 3 billion cubic yards of material, including rock, ash, pumice, snow, and ice was deposited directly north of the mountain in the upper 17 miles of the valley. Following the eruption, mudflows quickly developed in the South Fork Toutle River, and in the Lewis River tributaries of Smith Creek, Muddy River, and Pine Creek. Several hours later a massive mudflow originated from the debris avalanche deposit in the North Fork Toutle River valley. This North Fork mudflow caused widespread destruction as it moved downstream through the lower Toutle and Cowlitz Rivers. This report describes the location and chronology of the mudflows which followed the May 18 eruption. Average velocities are presented for the mudflows in the South and North Fork Toutle Rivers, and photographs illustrate the character of the debris and mud deposits. (USGS)

CHANNEL CONDITIONS IN THE LOWER TOUTLE AND COWLITZ RIVERS RESULTING FROM THE MUDFLOWS OF MAY 18, 1980,
Geological Survey, Tacoma, WA. Water Resources Div.
R. E. Lombard, M. B. Miles, L. M. Nelson, D. L. Kresch, and P. J. Carpenter.
Available from the Br. of Distr., USGS, 604 S. Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-C, 1981. 16 p, 13 Fig, 1 Tab, 9 Ref.

Descriptors: *Volcanoes, *Floodwater, *Flood control, *Mudflows, Sediments, Dredging, Flood protection, Flood plains, Runoff, Flood forecasting, Maximum probable floods, *Washington, *Mount St. Helens, Toutle River, Cowlitz River, Castle Rock.

The volcanic eruption of Mount St. Helens on May 18, 1980, triggered mudflows on the South and North Forks of the Toutle River that deposited up to 15 feet of sediment in the channels of the lower Toutle and Cowlitz Rivers. The thickness of the sediment deposited on the flood plain ranged from almost none just upstream from Kelso to about 10 feet near Castle Rock and the mouth of the Toutle River. Existing levees in Castle Rock, Kelso, and Longview contained the mudflows and prevented flooding of those communities. The

mudflow reduced the within-channel flow capacity, except at Kelso and Longview where the effect was minor. The potential exists for unusually high flood levels, up to 10-feet higher than normal, from autumn and winter precipitation. Planned flood-alleviation measures include dredging, additional levees, and sediment-retention structures. A flood-warning system has been established, and the current potential for flooding is being monitored through continued surveillance of the river system. (USGS)

POLYCHLORINATED BIPHENYL TRANSPORT IN THE HUDSON RIVER, NEW YORK,
Geological Survey, Albany, NY. Water Resources Div.
J. T. Turk, and D. E. Troutman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-249757, Price codes: A02 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-9, 1981. 11 p, 5 Fig, 2 Tab, 3 Ref.

Descriptors: *Water quality, *Polychlorinated biphenols, *Suspended solids, *Pollutants, River flow, Wastewater disposal, Sediments, Suspended sediments, *New York, *Hudson River, Resuspension, Point discharge, Path of pollutants.

Polychlorinated biphenyls (PCB's) have been entering the Hudson River estuary since 1951. Concentration and loading of PCB's in the river below Waterford, N.Y., are controlled at present by resuspension of sediments containing these substances; therefore, until the amount of PCB's in the sediments is significantly lowered, reduction of point-source PCB discharge from the present rate of 0.4 kilograms per day will produce no more than a 10% reduction in loading to the river. Potential concentrations of PCB's in solution and suspension in the river can be predicted by a simple model for mixing and dilution. From a known range of PCB influent rates, total PCB loading to the Hudson River from above Waterford is shown to be between 2,000 and 12,000 kilograms per year. (USGS)

Descriptors: *Water quality, *Streams, *Polychlorinated biphenols, *Sediment transport, Pollutants, Geohydrology, Sediments, Phosphorus, Heavy metals, Suspended sediments, Chemical analysis, Least squares method, *New York, *Hudson River, Resuspension.

Water samples from two Hudson River floods in 1977--one originating mainly in shale subbasins that produce high sediment loads, the other in soil-poor, crystalline rock terrane that yields little sediment--were analyzed to evaluate the relationship of iron, manganese, lead, phosphorus, and polychlorinated biphenyls (PCB's) to suspended-sediment concentration. During the flood of high sediment discharge, ratios for all substances studied except PCB's reflected their concentration within the basin regolith. During the flood of smaller magnitude, from the low-sediment crystalline terrane, however, only the ratio for iron correlated with predicted concentrations in the basin, which suggests that the chemical constituents studied were contributed principally from other sources, possibly anthropogenic sources. High lead concentrations in the low-sediment flood were derived from an unidentified, basinwide source whose contribution was relatively insignificant during the flood from the shale area. (USGS)

EVALUATION OF THE MALAGA BEND SALINITY ALLEVIATION PROJECT, EDDY COUNTY, NEW MEXICO,
Geological Survey, Albuquerque, NM. Water Resources Div.
J. L. Kunkler.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $4.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 80-1111, September 1980. 31 p, 5 Fig, 4 Tab, 20 Ref.

Descriptors: *Brines, *Rivers, *Water quality, *Salinity, Reservoirs, Leakage, Water analysis, Aquifers, Evaluation, *New Mexico, Eddy County, Pecos River, Malaga Bend.

In an effort to reduce the flow of brine springs in the Malaga Bend reach of the Pecos River in southeastern New Mexico, brine was pumped from an aquifer underlying the Malaga Bend reach to a local depression known as Anderson Lake. The attempt to improve the quality of river water with this experiment was not successful because brine leakage from Anderson Lake to the nearby Pecos River through permeable subsurface rocks was greater than the previous natural spring inflow. Brine leakage from Anderson Lake from July 22, 1963, through September 30, 1968, was estimated by evaporation-pan, salt accumulation, and dissolved-constituent methods. The leakage values given by these three methods are in good agreement with each other and indicate that between the dates given, leakage from the lake was about 2,300 acre-feet, compared with a brine inflow to the lake of about 3,690 acre-feet. Other data indicate that pumping from the brine aquifer greatly reduced the natural inflow from brine springs to the Malaga Bend reach. The rate of brine leakage from Anderson Lake is probably greater than might be expected from other brine lakes in the area because the cavities in the bottom of the lake apparently are in hydrologic connection with the Pecos River. This connection is shown by a relation between the salinity of the Pecos River and the reservoir stage of Anderson Lake. (USGS)

CARBON ISOTOPES AS INDICATORS OF THE SOURCE AND FATE OF CARBON IN RIVERS AND ESTUARIES,
Geological Survey, Reston, VA.
E. C. Spiker.
Available from the National Technical Information Service, Springfield, VA as CONF-8009140, Price codes: A18 in paper copy, A01 in microfiche. In: Flux of Organic Carbon by Rivers to the Oceans, Report of a Workshop, Woods Hole, MA, Sept 21-25, 1980, Dept. of Energy Report CONF-8009140, April 1981. p 75-108, 6 Fig, 2 Tab, 44 Ref.

Descriptors: *Carbon radioisotopes, *Carbon cycle, *Indicators, *Tracers, Vegetation, Estuaries, Rivers, Organic carbon.

The double isotopic labeling of carbon is particularly useful for the analysis of sources and sinks of carbon. The onset of nuclear weapons testing in 1954 resulted in a large input of bomb-produced excess carbon-14. The spread of bomb carbon-14 through the terrestrial carbon pool offers considerable potential in resolving the question of whether an increase in carbon transport by rivers might be due to increased photosynthesis or to increased soil erosion, by determining the time of fixation by photosynthesis. Delta carbon-13 is a relatively simple and reliable source indicator that can discriminate between terrestrial and marine organic carbon. A comparison of delta carbon-13 distributions in the San Francisco Bay and the Potomac River estuary demonstrates the varying importance of estuarine primary productivity in different systems. The analysis of both carbon-14 and carbon-13 provides unique information about the derivation and processing of carbon in rivers. The usefulness of these techniques is of course greatly enhanced when applied in conjunction with other tracers, such as nitrogen-15, C/H/N ratios, and various organic compounds. Delta nitrogen-15 may be very useful if it can distinguish between fresh-water aquatic plants and land plants. The new solid-state carbon-13 NMR techniques should provide a powerful tool that can discriminate between algal and vascular plant carbon. (Moore-SRC)

Descriptors: *Indicators, *Tracers, *Organic matter, *Biochemistry, *Water pollution sources, Carbohydrates, Lipids, Proteins, Organic compounds, Estuaries, Terrestrial plants, Lignins.

Almost all molecular tracers used to distinguish the geographic or biological sources of organic matter in natural environments are derived from photosynthetic plants. Molecular organic indicators can be classified in terms of the four major categories of plant natural products: carbohydrates, proteins, phenolics (primarily lignins), and lipids. Higher land plants, which are composed primarily of cellulose and lignin, contain relatively little organic nitrogen. C/N ratios have been used to establish the presence of land derived organic matter in sediments and suspended particulate matter, but the wide range of C/N values in higher plants and the effects of diagenesis are a disadvantage. Of the carbohydrates, the natural sugars and uronic acids have some potential for use as terrestrial tracers. Lignins are the only major biochemicals to have an unambiguous terrestrial origin. Lignin-derived phenols can be used to obtain information concerning the taxonomic and tissue sources of lignin mixtures, and to estimate quantitatively the amount of vascular plant remains. This lipids include a variety of molecular types that can be applied as terrestrial tracers. Leaf wax hydrocarbons have been used extensively to trace higher-plant lipids in rivers, estuaries, and the open ocean. Certain tricyclic diterpenoid hydrocarbons are also used as terrestrial source indicators. Linear, unsaturated fatty acids are a major lipid component of higher plants, and can be used as indicators of land-derived material. Diterpenoid resin acids are also useful terrestrial source indicators. Sterols are useful geochemical tracers because of their relatively high chemical stability and taxonomically related structural diversity. (Moore-SRC)

MODELING PHOSPHORUS LOADING AND LAKE RESPONSE UNDER UNCERTAINTY: A

URBANA-CHAMPAIGN

MANUAL AND COMPILATION OF EXPORT COEFFICIENTS.
Environmental Protection Agency, Washington, DC.
Report EPA-440/5-80-011, June 1980. 223 p, 22 Fig, 31 Tab, 195 Ref, Append.

Descriptors: *Mathematical models, *Phosphorus, *Cycling nutrients, *Eutrophication, Pollution load, Land use, Trophic level, Air pollution, Error analysis, Precision, Prediction, Lakes, *Limnology, Environmental effects.

A procedure is proposed that may be used to quantify the relationship between land use and lake trophic quality. The methodology is based on an input-output phosphorus lake model. When it is employed to predict the impact of projected land use changes, it is necessary to use phosphorus export coefficients extrapolated from other points in time and/or space. These coefficients represent the mass loading of phosphorus to a surface water body per year per unit of source. Nitrogen and phosphorus export coefficients from different land uses including forest, crops, pasture and grazing land, urban, septic tanks and absorption fields, and sewage treatment plants are given. The impact of atmospheric inputs is noted. The criteria for selecting the appropriate coefficients are: accuracy, precision, representativeness, temporal extent of sampling, nutrient flux estimation, and concentration and flow data. The model includes an error estimation procedure, and is applicable to a fairly wide range of lake types. The limitations of the methodology involve uncertainties in the input information and their impact on prediction precision. (Brambley-SRC)

QUALITY OF WATER IN TIBBEE CREEK AND TRIBUTARIES NEAR WEST POINT, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
S. J. Kalkhoff.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $6.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-406, 1981. 42 p, 7 Fig, 3 Tab, 12 Ref.

Descriptors: *Water quality, *Surface water, *Streamflow, *Hydrologic data, Sampling, Water analysis, Bacteria, *Mississippi, Tibbee Creek, Town Creek, Catalpa Creek, Path of pollutants.

An intensive water-quality study was conducted on Tibbee Creek and two of its tributaries, Town Creek and Catalpa Creek, on June 19-22, 1979. The data were collected during a period of low discharge and high air temperatures. The water in Tibbee Creek and Catalpa Creek was of much better quality than water in Town Creek. Large quantities of nitrogen, phosphorus, and dissolved solids and high densities of fecal coliform were present in Town Creek. The five-day biochemical oxygen demand values averaged 14 mg/L, and the mean total nitrogen concentration was 56 mg/L. The mean concentrations of ammonia, nitrate plus nitrite nitrogen, and organic nitrogen were 1.8 mg/L, 50 mg/L, and 3.7 mg/L, respectively. A total phosphorus load of more than 400 pounds per day, more than 91% of the total phosphorus load leaving the study area, was carried by Town Creek into Tibbee Creek. Total phosphorus concentrations averaged 14 mg/L in Town Creek and 0.11 and 0.12 mg/L in Tibbee and Catalpa Creeks respectively. Bacterial densities were higher at site 2 in Town Creek than at sites 1 and 3 in Tibbee and Catalpa Creeks respectively. The median fecal coliform bacterial density was 25,000 col/100 mL (colonies per 100 milliliters) in Town Creek and less than 200 col/100 mL in Tibbee and Catalpa Creeks. Median fecal streptococcal densities were 1,000 col/100 mL in Town Creek, 210 col/100 mL in Tibbee Creek, and 800 col/100 mL in Catalpa Creek. Fecal coliform to fecal streptococcal ratios were greater than 4.0 in Town Creek, indicating wastes of human origin were probably present during the study. Ratios were less than 0.7 in Tibbee and Catalpa Creeks, indicating human wastes were probably absent during the study. (USGS)

EFFECT OF AGRICULTURAL LAND DEVELOPMENT ON DRAINAGE WATERS IN THE NORTH CAROLINA TIDEWATER REGION,
North Carolina State Univ. at Raleigh.
R. W. Skaggs, J. W. Gilliam, T. J. Sheets, and J. S. Barnes.
Environmental Protection Agency Project Summary EPA-600/S3-80-087, July 1981. 3 p.

Descriptors: *Agricultural runoff, *Drainage, Water quality, *Pesticide residues, *Agricultural hydrology, *Land development, Land use, Nitrogen, Phosphorus, Organic soils, Herbicides, Coliforms, Evapotranspiration, Pesticide drift, Subsidence, *North Carolina, *Tide lands.

In a three-year study, the effect of agricultural drainage and development on hydrology and the effect of runoff water quality on high organic soils were examined in the North Carolina Tidewater Region. A small but significant increase was found in organic nitrogen in drainage water as a result of agricultural development. True organic soils lost considerably more phosphorus to drainage waters. Development caused a decrease in evapotranspiration with a consequent small increase in annual outflow even during years when droughts occurred. Dissolved oxygen, biochemical oxygen demand, temperature, pH, and other water quality parameters exhibited relatively small changes as a result of development. A significant increase in the loss of fecal and total coliform bacteria from pasture land was observed, which represents a potential water quality problem. Studies of the herbicide alachlor showed that it disappeared rapidly from soil after application but also showed that low, nonphytotoxic concentrations persisted from one season to the next. High concentrations in drainage waters appeared to be caused by direct spraying or by spray drift. Soil subsidence was greatest immediately after development.

AN EMPIRICAL EQUATION FOR PREDICTING SOLUBLE PHOSPHORUS LOADS FROM AGRICULTURAL WATERSHEDS,
Wisconsin Univ.-Madison. Water Resources Center.
B. A. Miller, and T. C. Daniel.
Transactions of the ASAE, Vol 24, No 2, p 375-381, 390, March-April, 1981. 8 Tab, 33 Ref.

Descriptors: *Phosphorus compounds, Land use, *Nutrients, Runoff, Regression analysis, Rainfall-runoff relationships, Fate of pollutants, Small watersheds, *Agricultural watersheds, Pollutant load, *Agricultural runoff.

An empirical equation was developed to predict soluble reactive phosphorus (SRP) loads from agricultural watersheds. This equation was derived from regression analysis of data on nutrient loading studies conducted on locations with Midwest-type climates. Factors affecting SRP loadings were precipitation, area, slope, soil type, land use, and farm practices. The equation was used to predict SRP loads from agricultural watersheds in Washington County, Wisconsin, based on 1976-1978 data. Predicted and observed loads were a function of land use, the percentage of land in hay having the most influence. Effects of fertilizer usage, depth of surface runoff, and tillage practices were not statistically significant. The equation does not account for weather and snowmelt variations nor for sediment-soluble P interactions. It is more accurate on small watersheds. (Cassar-FRC)

SEDIMENT AND NUTRIENT MOVEMENT FROM THE BLACK CREEK WATERSHED,
Purdue Univ., Lafayette, IN. Dept. of Agricultural Engineering.
E. J. Monke, D. W. Nelson, D. B. Beasley, and A. B. Bottcher.
Transactions of the ASAE, Vol 24, No 2, p 391-395, 400, March-April, 1981. 1 Fig, 14 Tab, 8 Ref.

Descriptors: *Sediment transport, *Nutrients, *Pollution load, Path of pollutants, Erosion, Phosphorus compounds, Nitrogen compounds, Snowmelt, Runoff, Rainfall, Nonpoint pollution sources, Agricultural runoff, Water quality, Black Creek, *Indiana, Maumee River, Lake Erie.

Discharge from the Black Creek Watershed, Indiana, was monitored to study the effects of nonpoint source pollution from agricultural runoff on water quality of the Maumee River, which flows into Lake Erie. Data from 1975, a high rainfall year (108.0 cm), and 1976, a low rainfall year (67.0 cm), were used. Two subbasins with contrasting soils and land uses were compared. The Dreisbach drainage area (gently rolling, glacial till) is more residential and has more grain and pasture. The Smith-Fry drainage area (lake plain and beach, nearly level) has few homes and 63% row crops. Runoffs were 26.0-29.1 cm in 1975 and 10.1-12.4 cm in 1976. Sediment yields (in kg per ha) were: Smith-Fry, 2130 in 1975 and 640 in 1976; Dreisbach, 3740 in 1975 and 380 in 1976; and Black Creek, 2370 in 1975 and 530 in 1976. Total N loadings (in kg per ha) were: Smith-Fry, 53.2 in 1975 and 10.3 in 1976; Dreisbach, 44.1 in 1975 and 6.6 in 1976; and Black Creek, 48.7 in 1975 and 8.6 in 1976. Total P loadings (in kg per ha) were: Smith-Fry, 5.4 in 1975 and 1.1 in 1976; Dreisbach, 5.0 in 1975 and 1.0 in 1976; and Black Creek, 5.2 in 1975 and 1.1 in 1976. More soluble inorganic P came from the residential Dreisbach area, and more nitrates from the Smith-Fry agricultural area. From 77 to 96% of P and about 50% of the N was bound to sediment transported. Large storms produced the greatest amount of sediment and nutrient transport. Therefore, continuous sampling is required for accurate assessment. During snowmelt, soluble P and other soluble nutrients were disproportionately high compared with snowmelt runoff. Sediments in the Black Creek contain three times the total P and five times the total N found in uneroded soils. (Cassar-FRC)
W82-00135

PREDICTING RUNOFF POLLUTANT REDUCTION IN BUFFER ZONES ADJACENT TO LAND TREATMENT SITES,

North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
M. R. Overcash, S. C. Bingham, and P. W. Westerman.
Transactions of the ASAE, Vol 24, No 2, p 430-435, March-April, 1981. 6 Fig, 5 Tab, 21 Ref.

Descriptors: *Animal wastes, *Land application, *Nonpoint pollution sources, *Water pollution control, Buffer zones, Model studies, Mathematical models, Infiltration, Runoff, Pollution load, Soil types, Rainfall-runoff relationships.

A mathematical model was developed to estimate the proper buffer zone length for preventing non-point source pollution from animal waste application sites. Three major factors were considered: pollutant concentration in runoff, dilution, and infiltration. A family of reduction percentages vs. buffer zone/waste area curves are presented. Soil type significantly affected buffer zone performance. For an infiltration rate/rainfall rate ratio of 0.7, characteristic of clay loam soil, a buffer area/length ratio of 1.0 is required to reduce pollutant concentrations by 90-100%. (Cassar-FRC)

CHARACTERISATION OF DOMESTIC AND INDUSTRIAL SEWAGE IN SOUTHERN CALIFORNIA COASTAL SEDIMENTS USING NITROGEN, CARBON, SULPHUR, AND URANIUM TRACERS,
California Univ., Los Angeles. Inst. of Geophysics and Planetary Physics.
R. E. Sweeney, E. K. Kalil, and I. R. Kaplan.
Marine Environmental Research, Vol 3, No 3, p 225-243, July, 1980. 9 Fig, 5 Tab, 15 Ref.

Descriptors: *Mathematical models, *Marine sediments, *Isotopic tracers, Sediments, Isotope studies, Wastewater, Nitrogen, Carbon, Sulfur, Uranium, Sedimentation, Water pollution effects, *San Pedro, California, Path of pollutants.

A degradation-mixing model was developed to aid in the interpretation of geochemical processes occurring in sewage-contaminated marine sediment near San Pedro, California. An effective tracer of sewage discharge in this area was the nitrogen isotope ratio. Uranium enrichment from seawater did not occur in the sediments contaminated by sewage. The uranium content of effluent particles was 18 ppm, while that for uncontaminated sediment was 5 ppm. This allows uranium content to also be a tool in tracing the deposition of the sewage sediment in the marine environment. Cadmium and sulfur, however, were not mobilized during sewage deposition and degradation. Data summarized by Morel et al. (1975) are presented and discussed in terms of the degradation-mixing model. About 30 to 40% of the discharged nitrogen and uranium in the particulates was lost during sedimentation. Cadmium is retained entirely in the sediment, and sulfur is further enriched by in situ reduction of seawater sulfate. (Small-FRC)

EFFECT OF KAOLIN CONCENTRATION ON DISTRIBUTION COEFFICIENT OF COPPER,
Maryland Univ. Eastern Shore, Princess Anne. Dept. of Natural Sciences.
G. C. Gupta, and F. L. Harrison.
Water, Air, and Soil Pollution, Vol 13, No 2, p 247-250, June, 1980. 1 Fig, 15 Ref.

Descriptors: *Copper, *Adsorption, *Kaolin, Fate of pollutants, Clays, Metals, Sediments, Mathematical equations, Laboratory studies.

Prior work on adsorption of copper by sediments and clays cannot be compared because a variety of clays and concentrations were used. In this study H-kaolin was equilibrated with Cu64 spiked water, shaken overnight in a constant temperature shaker, filtered through a 0.45 micrometer Millipore membrane, and the partitioning of radioactivity between filtrate and filter measured with a gamma ray well counter. The pH was stable at 6.37-6.42. Adsorption of Cu, expressed as the distribution coefficient, as a function clay concentration decreased sharply from over 7,000 at 10 ppm clay to 2,000 at 150 ppm and 1,2000 at 480 ppm. This curve agrees with other work in which higher adsorption occurs at lower concentrations and reaches an equilibrium at higher concentrations. The higher adsorption at lower concentrations may be caused by higher particle aggregation of the metal with the suspended clay. (Cassar-FRC)

HYDROLYSIS OF FENITROTHION IN MODEL AND NATURAL AQUATIC SYSTEMS,
Dept. of Agriculture, Ottawa (Ontario).
R. Greenhalgh, K. L. Dhawan, and P. Weinberger.
Journal of Agricultural and Food Chemistry, Vol 28, No 1, p 102-105, January/February, 1980. 4 Fig, 2 Tab, 18 Ref.

Descriptors: *Fenitrothion, *Natural waters, *Degradation, Pesticides, *Insecticides, Lakes, Photolysis, Microbial degradation, Hydrolysis, Chemical reactions, Fate of pollutants.

Fenetrothion can enter aquatic systems directly or indirectly, from surface runoff, after aerial application to forests. The degradation of fenitrothion, O,O-dimethyl O-(3-methyl-4-nitrophenyl) phosphorothioate, was studied in the dark in buffered distilled water, natural lake water, and buffered lake water. Above pH 8, 3-methyl-4-nitrophenol was formed by specific base catalysis. Below pH 7, demethylfenitrothion was formed by dealkylation. This reaction was temperature dependent. Aminofenitrothion appeared in reaction mixtures involving lake water, but not distilled water; in buffered lake water aminofenitrothion comprised 16% of the reaction products and in natural lake water, 5%. Buffering probably supports growth and activity of degrading microorganisms. Photolysis and microbial degradation are suggested as the main mechanisms for degradation of fenitrothion in natural aquatic systems because the half-life for disappearance in natural lake water (23C and pH 7.5) was 49.5 days in the dark and 1.5-2 days in the field. (Cassar-FRC)

FENITROTHION SPRAYED ON A POND: KINETICS OF ITS DISTRIBUTION AND TRANSFORMATION IN WATER AND SEDIMENT,
National Water Research Inst., Burlington (Ontario).
R. J. Maguire, and E. J. Hale.
Journal of Agricultural and Food Chemistry, Vol 28, No 2, p 372-378, 1980. 4 Fig, 3 Tab, 36 Ref.

Descriptors: *Fenitrothion, *Degradation, *Kinetics, Pesticides, *Insecticides, Suspended solids, Sediments, Adsorption, Hydrolysis, Chemical reactions, Volatility, Fate of pollutants, *Ponds, New Brunswick, Canada.

Fenitrothion, O,O-dimethyl O-(p-nitro-m-tolyl) phosphorothionate, sprayed on the surface of a pond in New Brunswick, Canada, to control spruce budworm, volatilized rapidly (half-time, 18 min at 20 degrees C). Concentrations of the insecticide in water, suspended solids, and sediments were below the detectable level two days after spraying. The most persistent degradation products were p-nitro-m-cresol in water (zero concentration reached at 48 hours) and aminofenitrothion in sediments (zero concentration reached in four days). Volatilization from the surface took place in two steps. Following the 'fast' volatilization, in which the fenitrothion probably codistilled with the formulation solvents, a second, slower process of volatilization from the subsurface water began. The half-life of this step was 64 days. Addition of 5 mg per liter of dissolved fulvic acid to the water retarded volatilization to a half-life of greater than 180 days. (Cassar-FRC)
W82-00159

PHOTOLYSIS OF N-NITROSODI-N-PROPYLAMINE IN WATER,
Lilly Research Lab., Greenfield, IN.
D. G. Saunders, and J. W. Mosier.
Journal of Agricultural and Food Chemistry, Vol 28, No 2, p 315-319, 1980. 4 Fig, 1 Tab, 16 Ref.

Descriptors: *Nitrosamines, *Degradation, *Herbicides, Fate of pollutants, Organic compounds, Nitrogen compounds, Amines, Photolysis, Chemical reactions, Trifluralin, Lakes, Natural waters, Carcinogens, Solar radiation.

Although N-nitroso-di-n-propylamine (NDPA) has not yet been detected in irrigation waters or pond waters, this trace contaminant of the herbicide trifluralin is a potential hazard in natural waters. The photolysis of NDPA was studied in lake water, in distilled water, and in waters buffered to pH 3, 6, and 9. NDPA rapidly degraded in all experiments. Concentrations of 1-100 ppm had little effect on the results. Photolysis rate was independent of pH. After 120 min the major photoproduct was n-propylamine (47-73%), with some di-n-propylamine (2-24%). (Cassar-FRC)
W82-00164

AMOUNTS AND RELATIVE SIGNIFICANCE OF RUNOFF TYPES IN THE TRANSPORT OF NITROGEN INTO A STREAM DRAINING AN AGRICULTURAL WATERSHED,
Massey Univ., Palmerston North (New Zealand). Dept. of Soil Science.
A. N. Sharpley, and J. K. Syers.
Water, Air, and Soil Pollution, Vol 15, No 3, p 299-308, April, 1981. 4 Fig, 3 Tab, 31 Ref.

Descriptors: *Runoff, *Nitrogen, Streamflow, *Agricultural watersheds, Watersheds, Agriculture, Agricultural runoff, Nutrients, Nonpoint pollution sources, Pollution load, Solute transport.

This paper reports an investigation of the relationships between flow and concentration of N forms; the sampling frequency required to reliably estimate the loading of N forms; the amounts of N forms transported in surface, accelerated subsurface, and subsurface runoff and stream flow; and the relative significance of the three runoff types to stream flow and nitrogen discharge from a watershed under pasture. The watershed under study was located adjacent to Massey University in Palmerston North, New Zealand. A slight decrease of NO3-N and an increase of particulate N concentrations was noted with increased flow of the runoff and the stream, due to dilution and increased sediment transport, respectively. The concentrations of NO3-N in surface, accelerated subsurface and subsurface runoff and stream flow, average over three years, was 0.3, 6.6, 4.8, and 4.6 mg/liter, respectively, amounting to 0.5, 9.4, 11.6, and 16.8 kg/ha/yr, respectively, transported annually. Although NO3-N accounted for only a minor portion of the total nitrogen transported in surface runoff, it was the major form of nitrogen transported in the other runoff types and in streamflow. Subsurface runoff contributed the major portion of stream discharge and NO3-N, particulate, and total N loadings of the stream. These findings are of interest in the study of non-point pollution of surface waters. (Baker-FRC)

ELEMENT MASS BALANCES FOR SOUTH CAROLINA COASTAL PLAIN WATERSHEDS,
South Carolina Univ., Columbia. Dept. of Geology.
L. R. Gardner.
Water, Air, and Soil Pollution, Vol 15, No 3, p 271-284, April, 1981. 1 Fig, 2 Tab, 27 Ref.

Descriptors: *Watersheds, *Chemical properties, Groundwater, *South Carolina, Coasts, Fertilizers, Precipitation, Runoff, *Agricultural chemicals, Path of pollutants, Chemistry of precipitation, Calcium, Solutes, Agricultural runoff.

An attempt was made to relate rainfall chemistry and agricultural and forestry practices to regional variations in water quality among the South Carolina Coastal Plain watersheds. The area is underlain by unconsolidated-to-poorly-consolidated sediments, ranging in age from late Cretaceous to Recent. The average annual precipitation over the Coastal Plain ranges from 114 cm along the western margin to 140 cm along the coast. Runoff from Upper Coastal Plain watersheds averages about 46 cm, compared to 33 cm for Lower Coastal Plain

watersheds. Fertilizers and liming materials appeared to be the major sources for Ca, Mg, K, Cl, and HCO3 inputs, whereas precipitation is the major source for Na and sulfates. Streamflow is the chief mode of output for all these elements. A balance between input and output is evident only for chlorides. Retentions of 50% or more are shown by Ca, Mg, K, HCO3 and SO4, whereas Na shows an apparent net loss. About 25% of the dolomitic liming materials applied to the landscape actually dissolve, and the carbonate chemistry of the Lower Coastal Plain streams is therefore probably largely controlled by seepage of groundwaters from underlying calcareous aquifers. K retention and Na loss may be due to cation exchange reactions on soil clays, whereas sulfate retention is due to reduction to H2S in floodplain environments and soil adsorption. (Baker-FRC)

Journal of Environmental Quality, Vol 9, No 3, p 434-442, July-September, 1980. 2 Fig, 8 Tab, 50 Ref.

Descriptors: *Carbon, *Decomposition, Plants, Animal wastes, Water quality, Monitoring, Model studies, Mathematical models, Nonpoint pollution sollution, Soil environment.

The available literature on organic carbon (C) transformations in soils treated with organic wastes was reviewed. A conceptual model to describe the fate of C in the soil-waste system was developed. The effects of soil, environment, and management factors on the rate of C decomposition was determined. The impact of C decomposition on the runoff transport of C and on water quality was described. The organic matter was obtained from three sources: animal waste, plant residues, and native soil organic matter. The model describes decomposition of wastes in two or three phases, assuming first-order kinetics at each phase. The fraction decomposed at each phase was determined graphically. Rapid decomposition of an easily decomposable C fraction in Phase I and II was followed by the decomposition of more resistant C fractions. The amount of C decomposed for plant residues in Phase I was significantly related to the log C/N ratio of the residue, whereas a similar relation was not noted for animal wastes. Decomposition rates were 6-10 times faster during Phase I and II decomposition as compared to Phase III. Kinetic rate constants, calculated at each phase of decomposition, were adjusted for the soil temperature, soil moisture, and method of application. Equations are presented to calculate the transport of waste particles and sediment-associated C in the runoff water. (Baker-FRC)

MODELING THE FLUX OF ATMOSPHERIC POLYCHLORINATED BIPHENYLS ACROSS THE AIR/WATER INTERFACE,
Wisconsin Univ.-Madison.
P. V. Doskey, and A. W. Andren.
Environmental Science and Technology, Vol 15, No 6, p 705-711, June, 1981. 4 Tab, 48 Ref.

Descriptors: *Air-water interfaces, *Polychlorinated biphenyls, *Mathematical models, Aroclors, Sampling, Measurement techniques, Deposition, Chemical analysis, Lakes, Lake Michigan.

Many freshwater lakes serve as sinks for polychlorinated biphenyls (PCBs), which are found throughout the environment. However, quantification of the total PCB flux across the air/water interface presents many problems. The total atmospheric PCB burden is analytically underestimated due to insufficient collection of the most volatile PCB fraction. Most quantification methods fail to indicate the extent of PCB mixture weathering. Speciation of airborne PCBs indicates that more than 90% exist in the vapor phase. Indirect calculations based on semiempirical expressions also suggest that particle-bound Aroclors are generally associated with submicrometer-size aerosols. Data from Lake Michigan are used to demonstrate a model of the PCB flux across the air/water interface. The model includes the processes of vapor and particle deposition, volatilization, and bubble ejection. Calculations indicate that atmospheric transport currently plays a major role in the deposition of PCBs in Lake Michigan in comparison with other modes of deposition. The importance of vapor deposition and volatilization is dependent upon the magnitude of the Henry's law constant. The role of bubble ejection in transferring PCBs from freshwater lakes back into the atmosphere is uncertain. A combination of approaches is needed to achieve an accurate picture of the atmospheric PCB flux. (Carroll-FRC)

PICLORAM DISSIPATION IN A SMALL SOUTHWESTERN STREAM,
Science and Education Administration, Tucson, AZ.
T. N. Johnsen, and W. L. Warskow.
Weed Science, Vol 28, No 5, p 612-615, September, 1980. 2 Fig, 1 Tab, 23 Ref.

Descriptors: *Picloram, *Streamflow, Degradation, *Herbicides, Dissipation, Environmental effects, Flow, Mixing.

The disappearance of a known amount of picloram (4-amino-3,5,6-trichloropicolinic acid) after injection into a small stream located in semiarid southwestern pinyon-juniper and interior chaparral woodlands was investigated. This herbicide is widely used in the southwest to control a variety of woody plants. The picloram was lost by normal flow actions such as the mixing of fast- and slow-moving water, and the interchange of surface and subsurface water in gravel and sand beds. The herbicide was injected at a concentration of 6.26 ppmw. It was detected in the following amounts in the stream: 0.943 ppmw at 0.8 km, 0.316 ppmw at 1.6 km, 0.014 ppmw at 3.2 km, 0.001 ppmw at 6.4 km, and none further downstream. Photodegradation tests were also performed, and sunlight decomposed 57% of the picloram after 8.8 hr of sunlight exposure. Little herbicide damage was observed on the day following injection, although algae growth may have been limited by the herbicide. (Small-FRC)

EVALUATION OF THE OVERLAND RUNOFF MODE OF LAND WASTEWATER TREATMENT FOR VIRUS REMOVAL,
Army Medical Bioengineering Research and Development Lab., Fort Detrick, MD.
S. A. Schaub, K. F. Kenyon, B. Bledsoe, and R. E. Thomas.
Applied and Environmental Microbiology, Vol 39, No 1, p 127-134, January, 1980. 3 Fig, 4 Tab, 12 Ref.

Descriptors: *Viruses, *Wastewater, Land disposal, Runoff, *Overland flow, Primary sludge, Sludge, Secondary wastewater, Advanced wastewater treatment, Bacteria, Bacteriophage, Adsorption, Poliovirus.

This study was conducted on an overland runoff treatment system in Ada, Oklahoma. The system and treatability parameters here were well characterized, and the raw and primary and secondary treated wastewater applied could be examined in identical soils, application regimes, and climatological conditions. Raw, primary, and secondary treated wastewaters were sprayed onto grass-covered 36 meter soil plots of fine sandy loam overlying an impermeable clay subsoil. Tracer bacteriophage f2 was seeded into the applied wastewaters, which were subsequently sampled at several points along the length of the plots. Assay of effluent samples revealed modest tracer virus removals of 30 to 60%. Data from timed experiments indicated that advancement of tracer virus to the bottom of the slopes proceeded at the same rate as wastewater, reaching the plot effluents within 50 to 90 minutes after application. Indigenous enteric virus levels were reduced by about 68 to 85% during migration down the treatment slopes. Soil sampling revealed that, although some f2 virus was found associated with the wastewater-saturated topsoil, little penetration of virus into the soil occurred. Lab soil adsorption studies revealed that poliovirus I was adsorbed much more readily than f2 virus. Comparison of virus removal during overland runoff with chemical removal of wastewater did not reveal any obvious correlations that could be used to predict virus removal. (Baker-FRC)

STAPHYLOCOCCUS AUREUS IN RURAL DRINKING WATER,
Oregon State Univ., Corvallis. Dept. of Microbiology.
M. W. LeChevallier, and R. J. Seidler.
Applied and Environmental Microbiology, Vol 39, No 4, p 739-742, April, 1980. 3 Tab, 23 Ref.

Descriptors: *Staphylococcus aureus, *Drinking water, *Rural areas, Well water, Water pollution sources, Plumbing, Chlorination, Water pollution prevention, Public health.

Coagulase-positive Staphylococcus aureus was isolated from over 6% of 320 drinking water specimen during routine monitoring of drinking water quality. Coliforms were detected in 49 of the samples. Only five times were coliforms and S. aureus detected simultaneously. Samples were collected from three points in household water systems to determine the source of S. aureus. Faucet screens were the most common reservoir of the highest S. aureus cell densities. Frequent cleaning of faucet screens, flushing of storage tanks, and, in cases of severe contamination, intermittent chlorination of rural water supplies would help eliminate various contaminants including S. aureus from domestic water supplies. This could lower the possibility of waterborne illness in rural water supplies. Well water was the most common water source in the study. (Small-FRC)

DISTRIBUTION AND TRANSPORT OF HEAVY METALS IN THE SEDIMENTS OF A SMALL NORTHERN EUTROPHIC LAKE,
Alberta Environmental Center, Vegreville.
J. W. Moore.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 6, p 828-833, 1980. 3 Tab, 15 Ref.

Descriptors: *Heavy metals, *Lake sediments, *Mine wastes, Metals, Mercury, Copper, Zinc, Arsenic, Strontium, Titanium, Chromium, Lead, Gold, Organic matter, Lakes, Path of pollutants, Sediments, Tailings, Water quality, Sorption, Distribution patterns.

Concentrations of heavy metals were measured in the sediments of a small, eutrophic lake, which received waste discharges from a gold mine between 1941 and 1949. Tailings in Thompsons Lake, Canadian Northwest Territories, contained an average of 190 micrograms per kg Hg, 57 mg per kg Cu, 93 mg per kg Pb, 100 mg per kg Zn, and 2100 mg per kg Ti. Cr, Sr, and As levels in tailings were much lower. In the sediments, Hg was high (440 micrograms per kg) nearest the mine and decreased with increasing distance away from the mine. Cu and Sr concentrations behaved similarly. Concentrations of Zn, Ti, As, Cr, and Pb in lake sediments were lower than in tailings; for all but Zn and As, the concentrations decreased at distances further from the mine. Evidently, tailings have not yet spread evenly throughout the lake, although the last wastes were deposited 30 years ago. Levels of Hg in water were generally less

than 0.2 mg per cu meter, with values of 2.5 and 0.5 mg per cu meter next to the mine. Concentrations of metals were strongly correlated with one another, indicating that the metals tend to move together. Organic matter in the sediment was 20-37% dry weight near the mine, 62-81% at 0.2 to 1.0 km from the mine, 65-87% at 1.1-2.0 km, and 68-91% at 2.1-3.0 km. There was a strong negative correlation between organic content and all metals but arsenic. (Cassar-FRC)

REDUCTION, METHYLATION, AND INCORPORATION OF ARSENIC INTO LIPIDS BY THE MARINE PHYTOPLANKTON DUNALIELLA TERTIOLECTA,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia). Marine Ecology Lab.
J. J. Wrench, and R. F. Addison.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 5, p 518-523, May, 1981. 4 Fig, 23 Ref.

Descriptors: *Arsenic compounds, *Lipids, *Phytoplankton, Dunaliella, Metabolism, Algae, Fate of pollutants, Marine algae, Arsenic.

The chemical forms of arsenic present in marine organisms affect its toxicity. This study is concerned with the reactions only within the first 45 min of exposure of the unicellular marine phytoplankton Dunaliella tertiolecta to As74 labeled arsenate. The algal cells synthesized three polar arsenic metabolites--arsenite, monomethylarsonic acid, and dimethylarsinic acid--and three arsenolipids. A large fraction of the assimilated As appeared in the lipid fraction. Equilibrium of the arsenic metabolites was approached within 30 min of exposure. Two of the arsenolipids were labile in acid solution, producing arsenite as a primary acid hydrolysis product. Acid-labile arsenolipid 1 was hydrolyzed by phospholipase D and was similar chromatographically to a product synthesized from phosphadityl inositol and arsenite. Arsenolipid 2, also an arsenite complex, was categorized as a neutral or zwitterionic glycolipid. Arsenolipid 3, stable on silicic acid columns and not an arsenite, also appeared to be a glycolipid. POLLUTION FROM LAND RUNOFF,
Great Lakes Basin Commission, Ann Arbor, MI.
W. C. Sonzogni, G. Chesters, D. R. Coote, D. N. Jeffs, and J. C. Konrad.
Environmental Science and Technology, Vol 14, No 2, p 148-153, February, 1980. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Runoff, *Water pollution sources, Lakes, Great Lakes, Agricultural chemicals, Phosphorus, Land use, Chlorides, Municipal wastes, Climates, *Nonpoint pollution sources.

Nonpoint sources of pollution affecting the Great Lakes were identified and the causes cited. Practical remedial measures were considered. Eight areas, representing the full range of land use activities in the basin, were selected for detailed study. Land factors, such as land form, land use intensity, and materials usage, were found to be necessary for inclusion along with general land use when an area is evaluated as a nonpoint pollution source. Land form characteristics include soil texture, soil type, surficial geology, physiography, and soil chemistry. Land use intensity, or degree to which land is developed, has a major impact on water quality. Any land practice that exposes soil to the erosive forces of rainfall and runoff represents an erosion and pollution hazard. High chloride levels were often found along transportation corridors as a result of highway deicing operations and other activities. A number of materials are applied to land in the Great Lakes region, one of the most influential being fertilizers and other agricultural chemicals. Pesticide residues may be carried in the runoff waters. Among the pesticides detected in the study of the Great Lakes were atrazine, simazine, DDT, dieldrin, endosulfan, lindane, endrin, and heptachlor. Guthion, though heavily applied in orchards and found in runoff water, decomposes rapidly. (Baker-FRC)

CONCENTRATION AND SIZE OF ASBESTOS IN WATER SUPPLIES,
Health Effects Research Lab., Cincinnati, OH.
J. R. Millette, P. J. Clark, M. F. Pansing, and J. D. Twyman.
Environmental Health Perspectives, Vol 34, p 13-25, February 1980. 6 Tab, 25 Ref.

Descriptors: *Drinking water, *Asbestos, Pipes, Natural waters, Storms, Potable water, Erosion, Industrial wastes, Stream discharge.

Evidence is presented which suggests that asbestos is a significant contaminant in a number of water supplies in the United States. Chrysotile, a serpentine mineral, is the most common asbestos variety found in water supplies, but some amphiboles have also been identified. The amphibole crocidolite has been found in some waters distributed through asbestos cement pipe. Amphibole fibers in Lake Superior have been primarily of the cummingtonite-grunerite series, of which amosite, a commercial asbestos, is a member. Amphiboles of the tremolite-actinolite series were found in the Pacific Northwest drinking water supplies. No fibers of anthrophyllite have been reported. Filtration and coagulation can control asbestos fibers. To provide fiber size distribution data on asbestos in drinking water, only direct transfer preparation methods with transmission electron microscopy are used. Available data on asbestos concentrations in United States water supplies as determined by transmission electron microscopy are tabulated. In natural water systems the weather plays an important part in varying the concentration of asbestos fibers in water over time. The erosion of natural serpentine rock and of asbestos waste piles undoubtedly increases or decreases depending on rainfall and stream flow. Current data suggests that the consumer is not exposed to constant concentrations of asbestos fibers above one million per liter in most cases. Fibers contributed by natural erosion are generally shorter than those contributed by asbestos cement pipe. (Baker-FRC)

PREDICTIONS FOR PARTICLE DEPOSITION ON NATURAL WATERS,
Battelle Pacific Northwest Labs., Richland, WA.
S. A. Slinn, and W. G. N. Slinn.
Atmospheric Environment, Vol 14, No 9, p 1013-1016, 1980. 2 Fig, 16 Ref.

Descriptors: *Deposition rates, *Aerosols, *Air-water interfaces, Air pollution, Natural waters, Turbulence, Particle size, Wind, Model studies, Fate of pollutants.

A simple model is presented for investigating the influence of particle growth on particle deposition on natural waters. If particle growth by water vapor condensation occurs in the humid region adjacent to the air-water interface, then the deposition velocity for particles with dry radii of 1 micrometer is independent of particle size and equal to the limiting value set by atmospheric turbulence. A formula for calculating deposition velocity is given. (Cassar-FRC)

A COMPARISON OF NITROGEN IN SHALLOW GROUND WATER FROM SEWERED AND UNSEWERED AREAS, NASSAU COUNTY, NEW YORK, FROM 1952 THROUGH 1976,
Geological Survey, Towson, MD.
B. G. Katz, J. B. Lindner, and S. E. Ragone.
Ground Water, Vol 18, No 6, p 607-616, November-December, 1980. 7 Fig, 5 Tab, 37 Ref.

Descriptors: *Groundwater, *Nitrogen, *Hydrogeology, *Landfills, *Streams, Sewage treatment, Leachate, Water quality, Ammonium, Toxicity, Management planning, Water sampling, Precipitation, Soil water, Water table, *Nassau County, New York.

Median nitrogen concentrations of groundwater and water from streams in Nassau County, New York were statistically analyzed on an areal and temporal basis and by individual well to compare concentrations of nitrogen in ground water beneath sewered and unsewered areas. The predominant contributions of nitrogen in groundwater in 1976 were from nonpoint sources such as cesspool effluents and domestic fertilizers. Other significant sources are exfiltration from sewers, rainfall, overland runoff to recharge basins, agricultural fertilizers, animal wastes, landfills, and sewage-treatment plants. Extensive future monitoring is necessary to account for the lack of a significant difference between nitrate concentrations of sewered and unsewered areas. (Titus-FRC)
W82-00277

AN EVALUATION OF SOURCES OF NITROGEN AS CAUSES OF GROUND-WATER CONTAMINATION IN NASSAU COUNTY, LONG ISLAND,
Cornell Univ., Ithaca, NY. Center for Environmental Research.
K. S. Porter.
Ground Water, Vol 18, No 6, p 617-625, November-December, 1980. 7 Fig, 4 Tab, 35 Ref.

Descriptors: *Groundwater, *Nitrogen, *Hydrogeology, *Landfills, *Streams, Sewage treatment, Leachate, Water quality, Ammonium, Toxicity, Management planning, Water sampling, Precipitation, Soil moisture, Water table, *Nassau County, New York.

The sources of nitrogen in Nassau County and their relative magnitudes, obtained from routine surveys, are evaluated. Two principal sources of nitrogen are human waste water and fertilized turf. The partial concentrations produced by fertilizers are sufficiently high, relative to those produced by human waste water, to produce considerable masking of the effects of sewerage. This masking will be compounded when additional sources such as precipitation and domestic animals are also included. Because of this, management of one source may not be effective. Management of water pollution sources other than sewerage should be considered. (Titus-FRC)

NATURAL ABUNDANCES OF 15N AS A SOURCE INDICATOR FOR NEAR-SHORE MARINE SEDIMENTARY AND DISSOLVED NITROGEN,
California Univ., Los Angeles. Inst. of Geophysics and Planetary Physics.
R. E. Sweeney, and I. R. Kaplan.
Marine Chemistry, Vol 9, No 2, p 81-94, April, 1980. 7 Fig, 4 Tab, 28 Ref.

Descriptors: *Marine sediments, *Nitrogen, *Isotope studies, Sediments, Coastal waters, Organic matter, Water pollution sources, Ammonium, *Santa Barbara basin, California.

Delta nitrogen-15 (15N) values for total nitrogen and dissolved ammonium were measured in Santa Barbara Basin sediment to determine the sources of nitrogen in marine sediments. Organic matter originating in the euphotic zone of the ocean may have a distinctive nitrogen isotope composition when compared to organic matter originating in terrestrial soils. Nitrogen isotope ratios were measured for 42 sediment samples of total nitrogen and 38 dissolved pore-water ammonium samples from Santa Barbara Basin sediment cores. Delta-15N values ranged from 2.89 to 9.4%, with a mean of 6.8% while pore water ammonium values ranged from 8.2 to 12.4% with a mean of 10.2%. The dissolved ammonium in the pore water is thought to be produced by bacterial degradation of marine organic matter. The isotopic ratio for terrestrially derived nitrogen is about 2%, and for marine derived is about 10%. (Small-FRC)

VIRAL TRANSPORT THROUGH SOIL COLUMNS UNDER CONDITIONS OF SATURATED FLOW,
Texas Univ. Center for Applied Research and Technology at San Antonio.
S. W. Funderburg, B. E. Moore, B. P. Sagik, and C. A. Sorber.
Water Research, Vol 15, No 6, p 703-711, 1981. 1 Fig, 5 Tab, 22 Ref.

Descriptors: *Viruses, *Soil types, *Adsorption, *Land disposal, Wastewater disposal, Path of pollutants, Fate of pollutants, Saturated flow, Organic matter, Cation exchange, Clays, Loam.

Movement of poliovirus 1, reovirus 3, and bacteriophage OX174 was studied in eight soils with a wide range of properties--cation exchange capacity, organic carbon content, pH 5.7-8.3, silt and clay content, bulk density, and specific surface area. Soils were sampled to a depth of 100 cm and packed into cylinders 10 cm in diameter, each containing one-third of the soil profile length. Columns were flooded with wastewater-virus mixture followed by distilled water for five complete cycles. Virus elution was cyclical. Total number of virus eluted was affected by differences in soil properties. Poliovirus retention in the soil was greatest in soils with high cation exchange capacity values, low organic matter and clay content. OX174 retention was greatest in soils with high organic carbon, high residence time in combination with low soil pH or percent clay. Cation exchange capacity in combination with either soil pH or specific surface area were important in reovirus retention. In general, agricultural type soils were most suitable for adsorbing enteric viruses from land-applied wastewater. (Cassar-FRC)

DEPOSITION OF HEAVY ELEMENTS ON BELGIAN AGRICULTURAL SOILS,
Laboratoire de Chimie Inorganique et Nucleaire, Louvain (Belgium).
J-L. Navarre, C. Ronneau, and P. Priest.
Water, Air, and Soil Pollution, Vol 14, p 207-213, 1980. 1 Fig, 2 Tab, 21 Ref.

Descriptors: *Soil contamination, *Heavy metals, Metals, Fertilizers, Agriculture, *Belgium, Path of pollutants, *Agricultural chemicals, Farms, Air pollution, Water pollution sources, Precipitation, Rainfall, Deposition, Fallout.

Wet plus dry deposition processes contributed more heavy metals to Belgian agricultural soils than did chemical fertilizers. Sampling was conducted for one year in 19 purely rural sites as far removed as possible from obvious contamination sources: chimneys, roads, etc. Metals clearly attributable to human origin were Zn, As, Se, Hg, Pb, Cd, and Sb. The sea atmosphere was responsible for the higher levels of Zn (from corroded roofing), Br, and Na found at seaside sites. Certain other metals reached higher levels near factories emitting these materials. Cd, Cr, and Ba were relatively uniform throughout the country. (Cassar-FRC)

BEHAVIOR OF DDT, KEPONE, AND PERMETHRIN IN SEDIMENT-WATER SYSTEMS UNDER DIFFERENT OXIDATION-REDUCTION AND PH CONDITIONS,
Louisiana State Univ., Baton Rouge.
R. P. Gambrell, C. N. Reddy, V. Collard, G. Green, and W. H. Patrick, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-213266, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S3-81-038, July 1981. 3 p.

Descriptors: *Pesticide residues, *DDT, *Kepone, *Permethrin, *Hydrogen ion concentration, *Redox potential, Sediments, Soil types, Aerobic conditions, Anaerobic conditions, Degradation, Chlorinated hydrocarbons.

The effects of physicochemical conditons on the persistence of pesticide residues were investigated to improve prediction of the fate and potential impacts of residues in various environmental compartments. Three pH levels, ranging from moderately acidic to mildly alkaline, were studied for each compound. Four redox potentials(-150,50,250, and 450 mv) ranging from strongly reduced (anaerobic) to well oxidized (aerobic) were studied. The insecticide-substrate combinations included in the project were DDT in a Mobile Bay (Mobile, Alabama) sediment material, Kepone in the sediment material of a tributary of the James River (Hopewell, Virginia) and Permethrin in an Olivier soil material (Baton Rouge, Louisiana). Sample aliquots were removed from the laboratory microcosms to determine the recovery of the added compounds with time. A substantial redox potential effect was noted for DDT where recovery decreased from the spiking level of around 25 ppm to less than 10% of the spiking level for DDT where recovery decreased from the spiking level of around 25 ppm to less than 10% of the spiking level n). A less rapid loss of DDT was noted at 50 mv (moderately reduced condition), but the pesticide appeared stable under better oxidized conditions during the 45-day incubations. The levels of Kepone recovered did not change appreciably during 56 days of incubation under any of the combination of imposed pH and redox potential conditions. The recovery of Permethrin was affected by both pH and redox potential conditions over 25-day incubations. Unlike DDT, Permethrin was lost more rapidly under oxidizing conditions. Increasing pH enhanced the loss of this compound over the range of redox potential levels studied. (Brambley-SRC)

ASSESSMENT OF OIL SHALE RETORT WASTEWATER TREATMENT AND CONTROL TECHNOLOGY - PHASES I AND II,
Monsanto Research Corp., Dayton, OH.
J. R. Klieve, G. D. Rawlings, and J. R. Hoeflin.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187288, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-081, May 1981. 5 p, 3 Fig.

Descriptors: *Oil shale, *Wastewater treatment, *Water pollution sources, *Wastewater composition, *Water reuse, Mine drainage, Leachates, Trace metals, Organic compounds, Dissolved solids.

Phases I and II of a five-phase project comprise surveys of literature and other information sources to obtain data on oil shale retorting technologies, wastewater sources and characteristics, potential wastewater uses, and potentially applicable treatment technologies. In-situ oil shale retorting is the source of three waste streams - mine water, retort water, and gas condensate - and surface retorting also produces three waste streams - gas condensate, product water, and spent shale pile leachate. Mine water is known to contain high levels of alkalinity, COD, chloride, fluoride, sulfate, boron and sodium, and significant trace metals. Retort wastewater and product wastewater contain high levels of most pollutants identified. Gas condensates contain high levels of ammonia, alkalinity, and organics, but lower levels of trace metals than the retort wastes. High levels of organics, TDS, sulfate and sodium have been found in spent shale pile leachate. Research on treatment of these waste streams has shown that a number of treatments are possible, depending on the intended use of the treated water, but that the research has generally been small-scale, and that there are significant unresearched areas. (Brambley-SRC)

HUMAN USE IN A DISPERSED RECREATION AREA AND ITS EFFECT ON WATER QUALITY,
Pacific Northwest Forest and Range Experiment Station, Seattle, WA.
H. H. Christensen, R. E. Pacha, K. J. Varness, and R. F. Lapen.
In: Recreational Impact on Wildlands Conference Proceedings, October 27-29, 1978, Seattle, Washington. Forest Service, Pacific Northwest Region, Portland, Oregon, 1979. p 107-119, 1 Fig, 4 Tab, 38 Ref.

Descriptors: Wilderness areas, *Recreation, *Camping, *Water quality, *Recreation wastes, *Environmental effects, Camp sites, Coliforms, Human wastes, Feces, Water pollution sources, Rainfall.

Potential problems are associated with increases in dispersed outdoor recreation. This study was conducted to determine the effects camping, style of camping, self-contained parties, human waste disposal, and rain have on water quality. Two camping sites were selected, one downstream from the other, in the Greenwater watershed, Washington. The campsites were close to the water, with high frequency and heavy concentration of human use, and had no formal, sanitary facilities, and were studied from May 1975 - July 1976. Few vehicles with self-contained toilets were used so most human waste was deposited on the ground around the sites. Total coliforms at the upstream site ranged from 2-6/100 ml and 2-14/100 ml at the downstream site, well within the range for general recreation and esthetic enjoyment but above the acceptable level for drinking water. The higher levels were associated with the weekend when more campers were present. The coliform counts were not lower when self-contained vehicles were present. The bacteria were rapidly transmitted to the river water, even in dry periods. Site differences could play a part in the differences observed, and there is a dilution factor involved at the downstream site. (Brambley-SRC)

WATER IN THE ELIZABETHTOWN AREA - A STUDY OF LIMESTONE TERRANE IN NORTH-CENTRAL KENTUCKY,
Geological Survey, Louisville, KY. Water Resources Div.
T. W. Lambert.
Geological Survey Water-Resources Investigations 79-53 (open-file report) 1979. 81 p, 23 Fig, 4 Plates, 16 Tab, 44 Ref.

Descriptors: *Groundwater, *Surface water, *Water quality, *Limestone, Carbonate rocks, Karst, Aquifers, Wells, Water level, Springs, Groundwater movement, Surface water-groundwater relations, Chemical analysis, Trace elements, Streamflow, Low flow, Floods, Climatic data, *Kentucky, Elizabethtown, Nolin River, *Available water.

An inventory of the water resources of a 240-square-mile area in north-central Kentucky is reported. It includes water distribution, chemical quality, water use, and principles of water occurrence and availability, and references. Nolin River is the only major stream in the area. Two of its tributaries, Valley Creek and North Fork Nolin River, have water withdrawn for public supply by Elizabethtown and Hodgenville. The quality of the water from the streams is typical of a limestone terrane. Ground water is also used for public supplies by Elizabethtown and Hodgenville and by two industrial plants. Many springs have flows of more than 0.25 cubic foot per second. Except for stock water, only three springs serve as a water source. Water from wells and springs is typical of limestone terrane. PRELIMINARY EVALUATION OF GROUNDWATER CONTAMINATION BY COAL-TAR DERIVATIVES, ST. LOUIS PARK AREA, MINNESOTA,
Geological Survey, St. Paul, MN. Water Resources Div.
M. F. Hult, and M. E. Schoenberg.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $24.25 in paper copy, $19.50 in microfiche. Geological Survey Open-File Report 81-72, January 1981. 57 p, 18 Fig, 6 Plates, 4 Tab, 41 Ref.

Descriptors: Groundwater, *Water quality, *Groundwater pollution, Water pollution sources, Chemical wastes, Aquifers, Glacial drift, Bedrock, Geohydrology, Aquifer characteristics, Wells, Water level fluctuations, Withdrawal, Groundwater movement, Flow rates, Path of pollutants, Infiltration, Chemical analysis, *Minnesota, St. Louis Park, *Coal-tar derivatives, Industrial wastewater.

Operation of a coal-tar distillation and wood preserving plant for 1918-72 in St. Louis Park, Minnesota, resulted in ground-water contamination. This report presents the results of the first year (1979) of an ongoing study. By 1932, water in the Prairie du Chien-Jordan aquifer, the region's major source of ground water, was contaminated 3,500 feet from the plant. The hydraulic characteristics of the Prairie du Chien-Jordan aquifer, its long contamination history, and fluctuating pumpage combine to creat a complex distribution of coal-tar derivatives observed in the aquifer. The Prairie du Chien-Jordan aquifer underlies the area at depths of 250 to 500 feet and is overlain by two bedrock aquifers (Platteville and St. Peter), two confining beds (Glenwood and basal part of St. Peter), and 70 to 100 feet of glacial drift. Multiaquifer wells in the area have permitted contaminated water from near-surface aquifers to flow downward into the Prairie du Chien-Jordan aquifer. Flow rates of 20 to 150 gallons per minute from the shallower aquifers into the Prairie du Chien-Jordan aquifer were observed in five wells. In the drift, a hydrocarbon fluid phase is moving vertically downward relative to the aqueous phase. Dissolved constituents in the drift and Platteville aquifer, the uppermost bedrock unit over most of the area, have moved at least 4,000 feet. Low-molecular-weight compounds are moving preferentially through the drift and Platteville aquifer system. (USGS)

COMPARATIVE STUDY ON ORGANIC CONSTITUENTS IN POLLUTED AND UNPOLLUTED INLAND AQUATIC ENVIRONMENTS - I. FEATURES OF HYDROCARBONS FOR POLLUTED AND UNPOLLUTED WATERS,
Tokyo Metropolitan Univ. (Japan). Dept. of Chemistry.
G. Matsumoto, and T. Hanya.
Water Research, Vol 15, No 2, p 217-224, February, 1981. 4 Fig, 3 Tab, 25 Ref.

Descriptors: *Organic compounds, *Water pollution sources, *Industrial wastes, Water pollution, Path of pollutants, Suspended solids, Aquatic environment, Fossil fuels, Pollutant identification, *Japan, Water analysis.

The hydrocarbon constituents of polluted river waters from the Tokyo area and unpolluted water bodies from the Ogasawara Islands were compared. In the river waters from the Tokyo area, n-alkanes with carbon chain lengths of 12 to 36, squalane and unresolved complex mixtures of hydrocarbons (UCMH) were found at levels of 0.026-14, 0.004-1.7, and less than 5-290 micrograms/liter, respectively. In the waters of the Ogasawara Islands, fro, 12-37 carbon compounds were found at levels of 0.042 5o 4.0 micrograms/liter. The presence of squalane, UCMH and even-carbon numbered n-alkanes were associated with artificial hydrocarbon sources such as industrial wastes, fossil fuels and their products. Odd carbon numbered n-alkanes were more predominant in the unpolluted waters, and originated mostly from algae and higher plants. Squalane and UCMH make up the major portion of the n-alkanes identified in the water samples and are associated with particulate matter in both polluted and non-polluted waters. (Geiger-FRC)

ENTERIC BACTERIAL CONCENTRATIONS IN RESERVOIR FEEDER STREAMS: BASEFLOW CHARACTERISTICS AND RESPONSE TO HYDROGRAPH EVENTS,
Leeds Univ. (England). School of Geography.
A. McDonald, and D. Kay.
Water Research, Vol 15, No 8, p 961-968, August, 1981. 4 Fig, 3 Tab, 24 Ref.

Descriptors: *Enteric bacteria, *Coliforms, *Catchment areas, Watersheds, Hydrographs, Water quality, Rainfall, Precipitation, Streams, Path of pollutants, Thruscross Reservoir, England.

The relationship between coliform bacterial concentration and stream hydrology was investigated within two multiple-use Pennine catchments. The River Washburn and the Capelshaw Beck catchments are located on feeder streams to the Thruscross Reservoir in northern England. The first sampling program defined the background diurnal fluctuations, while the second phase defined the bacterial concentration during a total of 11 hydrograph events. During each hydrograph event on Capelshaw Beck an increase in total coliform and E. coli concentrations occurred at statistically significant levels. During the six River Washburn hydrographs, total coliforms increased significantly on five occasions, and E. coli increased significantly on four occasions. E. coli concentration during high flow conditions in both of the streams exceeded guidelines for direct contact recreational activities. The store of organisms may be located in bottom sediments, fecal material along the shore, or soil. It should be noted that management practices which affect the hydrological response of a catchment to rainfall are likely to cause changes in the enteric bacterial concentration of catchment streams. (Small-FRC)

UNDERSTANDING ACID RAIN,
S. Budiansky.
Environmental Science and Technology, Vol 15, No 6, p 623-624, June, 1981.

Descriptors: *Acid rain, *Sampling, *Pollutant identification, Precipitation, Rainfall, Water pollution effects.

Acid rain is a complex phenomenon which involves almost every component of the biosphere. The intensity and effects of acid rain may be affected by varying weather, varying soils, the presence of other pollutants, and species differences. Investigations of the effects of meteorological factors on amounts of chemical wet deposition have identified a number of systematic relationships. Cold fronts and squall lines, thunderstorms, and summer rainfall were all found to be associated with increased concentrations of hydrogen plus ions and sulfates. A considerable proportion of the available data on acid rain, both current and historical, is disjointed and based on inadequate sampling procedures. Much of the data does not include direct measurements of pH. Methods used to measure dry deposition are particularly inadequate, relying on such surrogate collectors as plastic buckets, which are incapable of measuring dry gaseous deposition. Study of the effects of acid rain on individual species often ignores the overall effect of the pollutant on the ecosystem as a whole and the effects of multiple pollutants on an individual species. Also, the amount of acidic material accumulated and absorbed into the soil will be affected by such subsequent events as runoff and snow melts. (Carroll-FRC)

ALKYLPYRIDINES IN SURFACE WATERS, GROUNDWATERS, AND SUBSOILS OF A DRAINAGE LOCATED ADJACENT TO AN OIL SHALE FACILITY,
Battelle Pacific Northwest Lab., Richland, WA.
R. G. Riley, T. R. Garland, K. Shiosaki, D. C. Mann, and R. E. Wildung.
Environmental Science and Technology, Vol 15, No 6, p 697-701, June, 1981. 3 Fig, 1 Tab, 16 Ref.

Descriptors: *Oil shale, *Alkylpyridines, *Hydrocarbons, Organic compounds, Bases, Solutes, Industrial wastes, Subsoil, Groundwater pollution, Surface water, Pollutants, Path of pollutants, Rifle, *Colorado.

Studies were conducted at the Department of Energy's Anvil Points Oil Shale Facility at Rifle, Colorado, to determine the concentration of water-soluble organic compounds in materials disposed of or stored at the site and in surface waters, ground waters, and subsoils above and below the site. Water from seeps and alluvial groundwaters downstream of the retorted shale disposal pile were found to have higher levels of total dissolved organic carbon than those upstream of the pile. Analysis of samples from one seep and one well below the disposal pile which had an odor similar to that of shale oil and retort water showed that alkylpyridines were present in these waters at 30.8 and 4.1 micrograms per milliliter, respectively. Surface waters of the stream below the seep were found to contain trace concentrations of alkylpyridines. Alkylpyridines were not detected in a sample of surface sediment from the stream located adjacent to the seep discharge, but were found with depth in cores of subsoil collected adjacent to the well containing alkylpyridines. While alkylpyridines were detected in retort water and in an aqueous extract of shale oil, they were not detected in aqueous extracts of raw shale, in retorted shale, nor in Prudhoe Bay crude oil. The presence of alkylpyridines in these samples in which such other water-soluble compounds as organic acids and phenols were absent suggests that the alkylpyridines were less subject to sorption on the soil or were more persistent during hydraulic transport. These compounds may be unique to shale oils,

UNIV. OF ILL. URBANA-CHAMPAIGN

perhaps allowing their use as diagnostic indicators of water in contact with shale oils at sites of oil shale production and processing. (Carroll-FRC)

TOXICITY AND ECOLOGICAL SIGNIFICANCE OF TRACE ELEMENTS IN AQUATIC ENVIRONMENTS,
Tennessee Univ., Knoxville.
E. V. Kalmaz.
Journal of Environmental Sciences, Vol 23, No 5, p 24-27, September/October, 1980. 1 Fig, 25 Ref.

Descriptors: *Toxicity, *Trace metals, *Contamination, *Water pollution, *Bioaccumulation, *Organic compounds, Stream pollution, Metals, Aquatic animals, Fish physiology, Food chains, Adsorption, Uptake, Ecosystems, Aquatic environment, Ecological effects.

The ecological signficance of trace elements in aquatic environments is discussed. To develop models for predicting the behavior of trace elements in aquatic systems, it is necessary to distinguish the various forms of chemical and physical states, such as solubility, adsorption capability, particle size, reactivity with other compounds and complex formation. Such characteristics determine the elements' availability to aquatic animals and plants. Sediment is a major source and sink for most trace elements. However, trace element concentrations vary over time and on a macro- and microgeographic scale. Bioconcentration factors tend to be higher for trace elements complexed with organic compounds and higher in aquatic than terrestrial systems. The present technology is not sufficient to quickly, inexpensively, and conclusively seek out a particular element, predict the effects of various dose levels and understand its behavior in aquatic environments. 5C. Effects Of Pollution

TOXICITY OF MOUNT ST. HELENS ASH LEACHATE TO A BLUE-GREEN ALGA,
Geological Survey, Lakewood, CO. Water Resources Div.
D. M. McKnight, G. L. Feder, and E. A. Stiles.
Available from Branch of Distr., USGS, 604 Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-F, 1981. 14 p, 6 Fig, 4 Tab, 9 Ref.

Descriptors: *Toxicity, *Cyanophyta, *Volcanoes, *Leachates, Algal toxins, Bioassay, Lakes, Organic compounds, Dissolved solids, Trace metals, Water quality, Chemical analysis, Water pollution effects, *Washington, *Mount St. Helens, Richland, Moses Lakes, *Volcanic ash.

This report describes laboratory studies with volcanic ash intended to aid the assessment of the possible effects of ash presence on the blue-green algal populations in lakes. Bioassays using leachate from volcanic ash of the May 18, 1980, eruption of Mount St. Helens, Wash., indicate that leachate derived from ash collected at Richland, Washington, is toxic to the blue-green alga Anabaena flos-aquae, whereas leachate from ash collected at Moses Lake, Wash., is not. The difference in the toxicity of the two leachates may be attributable to differences in concentration of cationic-exchangeable, dissolved, organic compounds. Seventeen percent of the dissolved organic carbon from the leachate from ash collected at Richland was retained on a cation-exchange column, whereas only six percent of the dissolved organic carbon from the leachate from ash collected at Moses Lake was retained. Anabaena flos-aquae cultures spiked with dilutions of 1 to 250 of leachate derived from volcanic ash collected at Richland showed toxic effects, whereas cultures spiked with a 1 to 25 dilution of leachate derived from ash collected at Moses Lake showed no toxic effects. The toxic components of the volcanic ash are nonuniformly distributed over the ash fall area. Preliminary data indicate that the toxic components may belong to one or more of the following classes of substances: (1) cationic organic compounds such as amines; (2) highly hydrophobic (sparingly soluble) organic compounds such as phenols that interact with and are retained by the cation-exchange-resin matrix; or (3) metal-organic complexes that are retained by interaction of the metal with the cation-exchange resin. EFFECTS OF THE MOUNT ST. HELENS ERUPTION ON THE BENTHIC FAUNA OF THE TOUTLE RIVER, MUDDY RIVER, AND PINE CREEK DRAINAGE BASINS, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
L. A. Fuste.
Available from the Branch of Distr., USGS, 604 Pickett St. Alexandria, VA 22304. Geological Survey Circular 850-H, 1981. 13 p, 3 Fig, 5 Tab, 6 Ref.

Descriptors: *Benthic fauna, *Volcanoes, *Ecosystems, Streams, Lakes, Sampling, Aquatic insects, Mayflies, Midges, Invertebrates, Aquatic habitats, *Washington, *Mount St. Helens, Toutle River, Muddy River, Pine Creek, Volcanic ash, *Ecological effects, *Surface water.

Benthic invertebrate samples were collected in the Toutle River, Muddy River, and Pine Creek drainage basins on March 28-30, 1980, to document pre-eruption conditions in watersheds surrounding Mount St. Helens in the event of a major eruption. A highly diverse fauna was present at all sampling sites. Mayfly and midge (chironomid) larvae were the most numerous organisms. An attempt was made to classify the streams studied according to the functional role of organisms in the processing of organic matter. It was hypothesized that many of the organisms exhibiting multiple functional roles in processing of organic matter were predominantly detritovores. This classification was then compared to a conceptual stream ecosystem model. The volcanic eruption of May 18 destroyed most, if not all, of the benthic fauna present at the sites sampled. The cataclysmic events that took place during the explosion modified the topography to the point of eliminating some of the watersheds, while in others the riparian vegetation was scoured out, along with the natural substrate of the streams. The potential for recolonization of stream benthos appears to be relatively high because of the creation of new habitats near backwaters and pools from springs which were exposed by the scouring action of the mudflows. It is believed that these 'seed habitats,' in conjunction with downstream drift from unaffected tributaries and aerial oviposition by winged adults of aquatic insects, will be the principal sources of stream benthos for the affected streams in the coming years. RECONNAISSANCE OF THE EFFECT OF LANDFILL LEACHATE ON THE WATER QUALITY OF MARSHALL BROOK, SOUTHWEST HARBOR, HANCOCK COUNTY, MAINE,
Geological Survey, Boston, MA. Water Resources Div.
B. P. Hansen.
Geological Survey Open-File Report 80-1120, 1980. 13 p, 3 Fig, 5 Tab, 14 Ref.

Descriptors: *Landfills, *Leachates, *Water quality, Surveys, Water pollution sources, Path of pollutants, Ammonia, Dissolved oxygen, Benthos, Specific conductivity, Chemical analysis, *Maine, *Marshall Brook, Southwest Harbor, Hancock County.

This report presents the results of a reconnaissance of surface-water quality in the Marshall Brook basin in Southwest Harbor, Maine. A small stream (2.2-square-mile drainage area) receiving leachate from a landfill was studied from August through November 1979 to determine the impact of the leachate on water quality. The presence of unionized ammonia, considered toxic to some aquatic vertebrates, was indicated in samples taken from sections of the stream affected by leachate. Some dissolved oxygen values did not meet the criteria for the protection of aquatic life. Many other dissolved constituents were present in elevated concentrations in the leachate-influenced reaches of the stream. Flow-data comparisons indicate that streamflow less than that observed will occur approximately 20% of the time. Leachate-affected stream conditions may deteriorate further during such low streamflow. Several areas with the potential for large sediment yields are present in the basin. (USGS)

ASSESSMENT OF 1978 WATER QUALITY CONDITIONS IN THE UPPER POTOMAC ESTUARY,
Environmental Protection Agency, Annapolis, MD. Annapolis Field Office.
L. J. Clark, S. E. Roesch, and M. M. Bray.
Available from the National Technical Information Service, Springfield, VA 22161 as PB80-212228, Price codes: A06 in paper copy, A01 in microfiche. Report EPA-903/9-80-002, March 1980. 102 p, 30 Fig, 12 Tab, 8 Ref, Append.

Descriptors: *Water quality, *Estuarine environment, *Water pollution effects, *Algal growth, Nitrogen, Phosphorus, Nutrients, Eutrophication, Dissolved oxygen, Effluents, Mathematical models, Chlorophyll a, Urban areas, Estuaries, *Potomac River estuary, District of Columbia area.

The challenge to improve the Potomac Estuary through reduction of point source pollutant loadings necessitates the periodic collection of field data to assess trends and the scope of existing water quality stresses. Ongoing efforts to improve and refine predictive mathematical models impose another need for extensive water quality information. The second successive intensive monitoring program in the Potomac Estuary was performed during the period July to September 1978. This program consisted of three distinct elements: slack tide sampling over a 65 mile reach of the upper estuary; sampling of the effluents at the eight major wastewater treatment plants in the Washington Metropolitan Area; and special field and labora-

tory studies which addressed specific aspects of the dissolved oxygen budget for mathematical modelling purposes as well as the chronic problem of eutrophication. The 1977 study occurred under low flows whereas the summer of 1978 was characterized by higher and more erratic flows, which were a major driving force in terms of water quality behavior. Comparing the 1977 and 1978 ambient N:P ratio data reveals that their rate of spatial decline, or the tendency for nitrogen to rate limit algal biomass production, appears to be a function of the bloom size as measured by chlorophyll a. Chlorophyll a concentrations in the Potomac during 1978 were low in comparison to 1977 observations and had considerably less variability. In September, blue-green algae comprised approximately 80% of the total population, and 87% of the blue-green population was identified as Pseudanabaena catenata. Blue Plains still constitutes, by far, the largest single point source in the Washington Metropolitan area, accounting for 85% of the BOD5, 77% of the TOC, and 58% of the inorganic PO4. (Moore-SRC)

THE AFTERMATH AT LONGVIEW,
Water Treatment Plant, Longview, WA.
L. E. Coplen.
Water/Engineering and Management, Vol 128, No 5, p 68-71, May, 1981.

Descriptors: *Volcanoes, *Water pollution effects, *Impaired water use, Disasters, Water treatment facilities, Alum, Costs, Suspended solids, Silt load, Temperature effects, Water supply, Longview, Washington, Mount St. Helens, Debris basins.

The effects of the eruption of Mount St. Helens on the Longview, Washington Water Treatment Plant are detailed. The eruption on May 18, 1980 caused logs and debris to clog the Cowlitz River, which is the plant's source of raw water. By Monday morning, May 19, the river water was steaming hot (90 degrees F) and the turbidity was above 70,000 JTU. The river was carrying millions of cubic yards of volcanic ash, pumice, silt, and wood debris. Water could not be treated at the Longview plant, so reservoir supplies were used, and water was also supplied by the nearby city of Kelso. Columbia River water was diverted to the plant from industrial sources. By Thursday the Cowlitz River water appeared treatable. Because the river water was constantly changing, alum feed rates had to be changed. Additional costs were encountered when sedimentation basins and mixing chambers began to fill once a month rather than once a year. Dredges had to work continuously to clean the river out. Also, additional personnel was required to meet increased operating and maintenance needs. (Small-FRC)
W82-00073

AN ANALYSIS OF FACTORS AFFECTING OXYGEN DEPLETION IN THE NEW YORK BIGHT,
Brookhaven National Lab., Upton, NY.
P. G. Falkowski, T. S. Hopkins, and J. J. Walsh.
Journal of Marine Research, Vol 38, No 3, p 479-506, 1980. 14 Fig, 4 Tab, 74 Ref.

Descriptors: *Oxygen, *Aquatic environment, *Organic loading, *Shellfish, Climatology, Carbon, Runoff, Precipitation, Zooplankton, Seasonal variation, Oxygen demand, Coastal waters, Hydrologic data, Water pollution effects, Climate, *Oxygen depletion, *New York Bight.

Historical data extending back to 1910 was analyzed in an attempt to distinguish between man-induced and natural causes of oxygen depletion in the New York Bight. Oxygen depletion is a common feature of areas of restricted flows. A causal chain of events led to the anoxic conditions observed in 1976. A warm winter with large runoff, a low frequency of spring storm events, a deep summer thermocline, persistent southerly winds with few reversals, a large autochthonous carbon load, and low grazing pressure all contributed to anoxia. Calculations suggest that anoxia could have occurred off the New Jersey coast in 1976 without any carbon loading from New York City, and that anoxia in this open shelf system can result from natural physical forcing and biological responses. (Titus-FRC)
W82-00106

AN AQUATIC RESPIROMETER FOR USE IN SUBLETHAL STUDIES,
Environmental Sciences Ltd., Vancouver (British Columbia).
W. S. Duval, R. P. Fink, and G. H. Geen.
Water Research, Vol 15, No 7, p 817-822, July, 1981. 4 Fig.

Descriptors: *Respiration, *Aquatic life, *Sublethal effects, Toxicity, *Toxins, Organic compounds, Respirometers, Oil, Water pollution effects, Fish, Salmon, Oxygen consumption, Bioindicators.

A computer-controlled respirometer system was developed to measure oxygen consumption of marine and fresh water organisms at regular intervals over a period of several days. It can be used to document physiological responses of aquatic organisms during and following exposure to sublethal concentrations of a toxicant. The apparatus consists of systems to supply seawater and toxicant, 5-liter glass respirometer vessels, a dissolved oxygen measurement system, light and temperature monitoring and control systems, and computer hardware and software. Tests conducted for several days on juvenile coho salmon (Oncorhynchus kisutch) showed that exposure to water containing 12.1 ppm aromatic hydrocarbons from a Prudhoe Bay crude oil fraction caused sharp increases in respiration rate at four hours exposure, followed by a return to normal at eight hours and subsequent depression. (Cassar-FRC)

RELATIONSHIP BETWEEN BIOTRANSFORMATION AND THE TOXICITY AND FATE OF XENOBIOTIC CHEMICALS IN FISH,
Medical Coll. of Wisconsin, Milwaukee. Dept. of Pharmacology and Toxicology.
J. J. Lech, and J. R. Bend.
Environmental Health Perspectives, Vol 34, p 115-131, February 1980. 10 Fig, 12 Tab, 75 Ref.

Descriptors: *Biotransformation, *Fish, Aquatic animals, Metabolism, Chemicals, Organic compounds, Water pollution, Polychlorinated biphenyls, Bioaccumulation, Toxicity, *Xenobiotic chemicals.

Some of the more recent developments in the study of the behavior of xenobiotic chemicals in aquatic species are reviewed. Specific examples are used to demonstrate the relationship between biotransformation and the toxicity, persistence and bioaccumulation of xenobiotic chemicals in fish. Many of the biotransformation reactions that have been described for xenobiotic substances in mammals have been demonstrated in fish, both in vivo and in vitro. Several of these reactions occur in fish at rates sufficient to exert significant effects on the toxicity and residue dynamics of selected chemicals. The inhibition of these reactions can lead to increased toxicity and bioaccumulation factors for certain chemicals. Several classes of compounds, including some polychlorinated biphenyls, are only metabolized slowly, and their disposition in fish may not be influenced to any great extent by biotransformation. Metabolites of compounds which are biotransformed rapidly may appear in certain fish tissues; in many instances these are not accounted for by conventional residue analysis methods. Microsomal mixed-function oxidases in several species of fish have been demonstrated to be induced by specific polycyclic aromatic hydrocarbons and by exposure of the fish to crude oil. Induction of these enzymes in fish can result in both qualitative and quantitative differences in the metabolic disposition of xenobiotics to which fish are exposed. (Baker-FRC)

TRANSFORMATION OF THE MOUSE CLONAL CELL LINE R846-DP8 BY MISSISSIPPI RIVER, RAW, AND FINISHED WATER SAMPLES FROM SOUTHEASTERN LOUISIANA,
Louisiana State Univ. Medical Center, New Orleans. Dept. of Microbiology.
W. Pelon, T. W. Beasley, and D. E. Lesley.
Environmental Science and Technology, Vol 14, No 6, p 723-726, June, 1980. 1 Fig, 4 Tab, 11 Ref.

Descriptors: *Public health, *Water pollution, *Drinking water, River water, *Raw water, Cultures, Human diseases, Mississippi River, Rivers, Carcinogens, Cell cultures, Organic compounds, Mutagens, Water analysis, *Mississippi.

A total of 118 river water, 70 raw water, and 115 finished water samples were collected over an 18-month period in Mississippi. Cultures of the mouse cell line R846-DP8 were exposed to the water samples. Nineteen of the samples (6%) induced morphological transformation of this cell strain. Transformation was noted with 7 (6%) Mississippi River samples, 7 (10%) raw water samples and 5 (4%) finished water samples. Transformations were not observed in less than four weeks of incubation. It is suggested that the small proportion of water samples which induced cell transformation was probably representative of a larger number which could have induced the changes, but were not detected either because of the limitations imposed by the methods employed or because of the criteria used for transformation. It is suggested that additional studies be made in this area, which could present a major public health problem. (Baker-FRC)

Applied and Environmental Microbiology, Vol 39, No 5, p 1010-1018, May, 1980. 2 Fig, 4 Tab, 33 Ref.

Descriptors: *Rivers, *Aeromonas, Bacteria, *Anacostia River, Sediments, *District of Columbia, Human diseases, Temperature effects, Aeromonas hydrophila, Aeromonas sobria, Water pollution, Seasonal variations, Wastewater, Wastewater outfall.

This study documents the occurrence and seasonal fluctuations of Aeromonas in the Anacostia River in Washington, D. C., where increased incidences of gastroenteritis and wound infections have occurred in personnel undergoing diver training operations throughout the year. The numbers of Aeromonas cells in Anacostia River sediment and water increased during periods of elevated water temperature, to maxima of 400,000 cells per g of sediment and 300 cells per ml of water. Correspondingly, Aeromonas counts dropped 2 to 4 logs as the water temperature decreased to 0 to 0.5 degrees C. Cultures taken by sterile swabs from the ears and face masks of divers after a 30 minute swim yielded bacterial types and numbers similar to those found in the river. The nasal passages of the divers apparently did not become contaminated by swimming, possibly because of the protective effect of the face masks used by the divers. Properties associated with virulence in A. hydrophila and A. sobria strains isolated from the river, sediment, and divers were investigated. Nearly 40% of the strains of both species collected during the study produced cytotoxic activity for mouse Y-1 adrenal cells, as well as elastase. Enterotoxin activity, as detected by the Y-1 assay, was observed in 3% of the strains of A. sobria and in 6% of the A. hydrophila strains. Fluid accumulation in rabbit ileal loops induced by both species of Aeromonas varied greatly among the 17 strains examined.

UNIV. OF ILL. URBANA-CHAMPAIGN

Fluid accumulation of at least 0.4 ml/cm was correlated with positive cytotoxin- or enterotoxin-like response in the Y-1 tissue culture assay. (Baker-FRC)

IMPACT OF CONSTRUCTION OF A HYDROELECTRIC PROJECT ON THE WATER QUALITY OF FIVE LAKES IN NOVA SCOTIA,
Department of the Environment, Halifax (Nova Scotia).
D. M. Kelly, J. K. Underwood, and D. Thirumurthi.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 173-184, 1980. 12 Fig, 3 Tab, 18 Ref.

Descriptors: *Water quality, *Erosion, *Environmental effects, Hydroelectric powerplants, Wreck Cove, *Nova Scotia, Construction, *Reservoir construction, Dam construction, Tunneling, Logging, Forest fires, Road construction, Vegetation effects, Lakes, Baseline studies, Monitoring.

Water quality of five highland lakes was monitored for 2.5 years during the construction of the Wreck Cove hydroelectric project, Nova Scotia, starting in February, 1975. Tunneling, dam construction, reservoir clear-cutting, slashing, burning, and building access roads had a pronounced impact on Surge Lake, and less on the other lakes--Big, Cheticamp, Gisborne, and Long. Ammonia and nitrate-nitrite concentrations in Surge Lake increased 833 and 7300%, respectively, following clear-cutting and initial construction activities; chlorophyll-a decreased by 1825%. Other water quality parameters which increased on the order of 50-450% were turbidity, suspended solids, conductivity, Ca, Mg, Na, K, and total and ortho-P. The following were more extreme in the Surge Lake watershed than in the other watersheds: slopes, intensity and length of construction, clear-cutting and burning, and a forest fire. In addition, soil was more erosive (less clay), and more vegetative cover, including roots, was removed. (Cassar-FRC)

Descriptors: *Acidic water, *Air pollution, Lakes, Sierra lakes, Hydrogen ion concentration, *Acid rain, Water pollution sources, Sierra Nevada.

Sierra lakes, most of which have little buffering capacity, showed little change in acidity during the last 15 years. Sampling of 170 lakes in 1965 resulted in an average pH of 6.0 (range 4.7 to 7.3). The mean 1980 pH's measured in 114 randomly selected Sierra lakes in July and October were 6.1 and 6.5, respectively. The higher fall pH probably reflects the seasonal effect of increased residence time of the water in the lake and associated buffering by lake sediments. Ten additional lakes where fish kills had occurred had mean pH of 6.6. (Cassar-FRC)

BEHAVIOR OF TRIFLURALIN IN AQUATIC MODEL ECOSYSTEMS,
Environmental Protection Agency, Beltsville, MD. Pesticide Degradation Lab.
R. S. Yockim, A. R. Isensee, and E. A. Walker.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 1, p 134-141, January, 1980. 5 Tab, 4 Ref.

Descriptors: *Ecosystems, *Pesticides, Trifluralin, Model studies, Ecology, Herbicides, Degradation, Fate of pollutants, *Water pollution effects.

The effects of trifluralin on the aquatic ecosystem were investigated in two different model ecosystems. In the first experiment the recirculating static model ecosystem was used. In the second experiment a continuous dosing system was designed to demonstrate the effect of direct application of trifluralin into the ecosystem. In both experiments organisms were sampled 1, 3, 7, 15, and 30 days after the start of the experiment. In the first experiment the amounts of trifluralin available for accumulation by the organisms depended on the rate of desorption from the soil. In the second, the actual water levels obtained were 0.8, 2.5, and 21.6 ppb in the 1, 10, and 100 ppb treatments, respectively, by day 30. The data indicated extensive variation that can be obtained when using different model ecosystem designs in studying the behavior of pesticides in the aquatic ecosystem. These differences were probably related to the rapid metabolism and degradation of soil-incorporated trifluralin in the first experiment and to the continuous input of trifluralin in the second experiment. A very important difference between the two ecosystems was the toxic effect of trifluralin on the algae and fish during the second experiment. It is concluded that the risks of trifluralin in the aquatic ecosystem are greatest when there is a continuous input of trifluralin. With occasional soil-incorporated input, the degradation processes would minimize the risk. (Baker-FRC)

EFFECTS OF HALOGENATED ORGANIC COMPOUNDS ON PHOTOSYNTHESIS IN ESTUARINE PHYTOPLANKTON,
Environmental Protection Agency, Gulf Breeze, FL. Gulf Breeze Environmental Research Lab.; and Environmental Research Lab., Johns Island, SC. Bears Fluff Field Station.
S. J. Erickson, and C. E. Hawkins.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 6, p 910-915, 1980. 6 Tab, 13 Ref.

Descriptors: *Estuarine environment, *Phytoplankton, *Chlorinated hydrocarbons, Toxicity, Water pollution effects, *Organic compounds, Cooling water, Photosynthesis, Wastewater treatment, Chlorination, Pentachlorophenol, Pentabromophenol, Phenols.

The effects of 15 organic compounds on photosynthesis in native estuarine phytoplankton were studied in outdoor aquaria. Some of the compounds tested are formed by chlorine biocides in cooling waters. Chloroform, bromoform, ethylene bromide, phenol, 4-bromophenol, and 2,4,6-trichlorophenol at concentrations up to 2.0 mg per liter did not affect C14 uptake by phytoplankton. Trichloroethylene stimulated C14 uptake at 0.5 to 1.0 mg per liter. Tetrachloroethylene inhibited uptake slightly at 2.0 mg per liter. C14 uptake expressed as % of control for concentrations of 0.5 to 2.0 mg per liter of other organic compounds were as follows: 2,4,6-tribromoanisole, 81-76%; 4-chlorophenol, 97-94%; 2,4,6-tribromophenol, 96-89%; pentachlorophenol, 39-2%; and pentabromophenol, 4 to -1%. Further tests with the two most toxic compounds, pentabromophenol and pentachlorophenol, at concentrations of 0.125 to 2.0 mg per liter showed that mixed phytoplankton were more sensitive to the chemicals than four individual phytoplankton cultures. Haloamines produced by metering NaOCl and NH4Cl into the aquaria were more inhibitory than either chemical separately. Chloramine T was not inhibitory to photosynthesis. (Cassar-FRC)

LETHALITY OF A SUSPENDED CLAY TO A DIVERSE SELECTION OF MARINE AND ESTUARINE MACROFAUNA,
Army Engineer Waterways Experiment Station, Vicksburg, MS.
V. A. McFarland, and R. K. Peddicord.
Archives of Environmental Contamination and Toxicology, Vol 9, No 6, p 733-741, 1980. 4 Fig, 3 Tab, 21 Ref.

Descriptors: *Suspended solids, *Kaolinite, Water pollution effects, Suspended load, Silicates, Clay minerals, Invertebrates, Pollutants, Laboratory studies, *Estuaries, *Fauna, Macrofauna, Estuarine environment.

The impact of suspensions of processed kaolinite, a common sheet-silicate clay mineral, on marine and estuarine macrofauna was investigated. The use of kaolinite permitted a study of the lethal effect of suspended particles themselves rather than the combined physical and chemical effects of sediments in various conditions of contamination. The flow-through system of 16 hemispherical 75-L aquaria supplied with kaolin and dilution water at estuarine or oceanic salinity was employed. A wide range of sensitivities was noted. Blue mussels measuring 2.5 cm in length reached 10% mortality after five days. The tunicate Ascidia ceratodes was the most sensitive species tested. In none of the tests could the LC50 value be calculated from the LC20 or LC10 values. There may have been a correlation between normal habitat of the species and sensitivity to suspended kaolin, although no phylogenetic correlations were apparent. No species that restricted itself to soft muddy bottoms was sensitive. All those species that were sensitive to high kaolin concentrations were either invertebrates occurring predominantly on sandy bottoms or in fouling communities, or fish not intimately associated with the bottom. PRIORITIZATION OF CHEMICALS ACCORDING TO THE DEGREE OF HAZARD IN THE AQUATIC ENVIRONMENT,
Dow Chemical Co., Midland, MI.
D. R. Branson.
Environmental Health Perspectives, Vol 34, p 133-138, February 1980. 3 Fig, 3 Tab, 15 Ref.

Descriptors: *Water pollution, *Priorities, Hazards, Assessments, Decision making, Planning, Regulations, Standards, Chemical analysis, *Water pollution effects.

As an alternative to arbitrarily listing or delisting chemicals for the purpose of priority control, this paper suggests a promising scientific approach to selecting priority chemicals based on the principles of hazard assessment for chemicals in the aquatic environment. According to the hypothesis employed, the highest priority chemicals are those with the smallest margin of safety, defined as the gap between the no-observable-effect concentrations and the ambient exposure concentrations. The no-observable-effect concentrations are based on the results of chronic or sensitive life stage tests with aquatic organisms and the acceptable daily intake rate for fish eaters. The ambient exposure concentrations are levels either measured in fish and water, or roughly estimated from a simple nomogram that requires only two of the following three factors: environmental release rate, ratio of dissipation to bioconcentration potential, or ambient residues in fish. The chemicals studied to illustrate this approach to prioritizing chemicals are: polychlorinated biphenyls, di-2-ethylhexyl phthalate, linear alkylbenzene sulfonate, and pentachlorophenol. PROJECTED TILE EFFLUENT EFFECTS ON THE OLDMAN RIVER,

Department of Agriculture, Lethbridge (Alberta). Irrigation Div.
D. B. Harker.
Canadian Water Resources Journal, Vol 6, No 2, p 65-75, 1981. 2 Fig, 1 Tab, 8 Ref.

Descriptors: *Water quality, *Tile drainage, Rivers, Oldman River, River flow, Flow, *Effluents, *Alberta.

Possible negative effects that tile effluent might have on the water quality of receiving systems such as the Oldman River were evaluated. The Irrigation Division of Alberta Agriculture conducted a program for three years, 1977-1979, to monitor effluent discharge and chemistries from 20 tile drainage sites. Projections were made concerning the possible effect of tile effluent on the water quality. Extremes in both tile and river flows were considered. Under conditions of average river flow, tile effluent is expected to have a minimal impact on river water quality in the near future. However, during periods of low river flow, future high tile discharges might substantially degrade water quality. The recent government announcement of an intent to build a regulating dam on the Oldman River within ten years may negate low flow conditions. Another alternative would be to direct drainage waters to large evaportion basins such as are presently under use or consideration in the Western United States. These basins have the disadvantage of needing high evaporation rates proportional to the storage area required. At present, much of the receiving water carrying tile effluent within Alberta contains high quality irrigation return flow, water that should be returned to the river. Another alternative could be to dilute saline river waters via interbasin transfer from a purer system. (Baker-FRC)

DEVELOPMENT OF BIOASSAY PROCEDURES FOR DEFINING POLLUTION OF HARBOR SEDIMENTS,
Wisconsin Univ.-Superior.
D. A. Bahnick, W. A. Swenson, T. P. Markee, D. J. Call, and C. A. Anderson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-178261, Price codes: A09 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S3-81-025, June 1981. 4 p.

Descriptors: *Bioassay, *Toxicity, *Sediments, *Water pollution sources, *Dredging, *Aquatic life, Interstitial water, Invertebrates, Aquatic animals, Metals, Polychlorinated biphenyls, DDE, Sunfish.

Reliable, cost effective procedures for identifying the potential effects of sediment chemical contaminants on water quality and aquatic communities are needed because of the continuous dredging of large volumes of sediments by the Corps of Engineers. Procedures studied include 96-hr toxicity tests employing Hexagenia limbata, Daphnia magna and Pontoporea affinis as biological probes, monitoring cough frequencies of bluegill sunfish in interstitial water derived from sediments, chemical analysis of sediment-water systems, and chemical analysis of chironomids and H. limbata exposed to the sediments. Sediment-water systems caused little toxicity in 96-hr exposure tests, although Daphnia was the most sensitive of these animals to toxicants. Similar cough frequencies were found for bluegill sunfish in dechlorinated city water compared to sediment interstitial water-Lake Superior water mixtures but it was observed that broken operculer patterns occurred in the interstitial water-Lake Superior Water mixtures. Most of the sediments used in the bioassay tests would be considered polluted according to at least one chemical parameter. Studies on extracting chemical species from the sediments showed that only small amounts could be readily extracted with Lake Superior Water. Evidence was found that chironomids dwelling in harbor sediments bioaccumulated PCBs and p,p'-DDE and possibly some metals. (Moore-SRC)

NATURAL VARIATION IN ABUNDANCE OF SALMONID POPULATIONS IN STREAMS AND ITS IMPLICATIONS FOR DESIGN OF IMPACT STUDIES,
Oregon State Univ., Corvallis. Dept. of Fisheries and Wildlife.
J. D. Hall, and N. J. Knight.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-198954, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S3-81-021, July 1981. 4 p, 1 Tab.

Descriptors: *Fish populations, *Water pollution effects, *Nonpoint pollution sources, *Salmon, Aquatic habitats, Environmental effects, Stream fisheries, Stream degradation, Ecosystems.

Salmonids are the principal fish species of economic importance affected by pollution in the Western United States. Assessment of damage to these fish populations cannot be undertaken without some understanding of the natural variation in abundance within and between populations. An extensive literature review relating to stock size and production of salmonid populations in streams was carried out to bring together data on the magnitude of natural variation in population size and to relate this variability to environmental conditions whenever possible. Temporal and spatial variation may be as high as several orders of magnitude, and are sufficient to mask significant perturbations caused by nonpoint source (NPS) pollutants. Environmental variables most closely associated with spatial variation are those relating to the quality of salmonid habitat, particularly physical characteristics such as cover. Streamflow and food abundance have been associated with both temporal and spatial variation. Considerable emphasis should be placed upon systems of rating habitat quality in attempts to minimize the effects of natural variation when evaluating the impact of NPS pollutants. As a means of more clearly separating natural variation from damage caused by NPS pollutants, more emphasis should be placed upon the study of basic processes in stream ecosystems and more extensive use should be made of paired comparisons in the design of impact studies. (Moore-SRC)

LONGITUDINAL SUCCESSION IN IMPACT ASSESSMENT OF RIVER SYSTEM FISH COMMUNITIES,
Argonne National Lab., IL.
R. M. Goldstein.
Water Resources Bulletin, Vol 17, No 1, p 75-81, February, 1981. 5 Fig, 2 Tab, 29 Ref. OWRT-A-052-CONN(21).

Descriptors: *Fish populations, *Environmental effects, *Rivers, Speciation, Longitudinal succession, Ecology, Aquatic habitats, Habitats, *Water pollution effects.

Longitudinal succession indicates an increase in diversity and species richness of fish communities with increasing river size. This is a result of increasing habitat complexity and environmental stability. Cultural impacts (agriculture, dam construction, pollution, introduced species) decrease the diversity, species richness, and evenness. Fish communities in 14 Connecticut and Rhode Island rivers were surveyed during the summer of 1974. Data was normalized to eliminate the bias caused by linear succession and compared with non-normalized data using regression analysis. The two sets of data were similar. Evenness, which is not affected by longitudinal succession, was the most sensitive parameter. Introduced species, such as centrarchids, cause errors because many increase in number with altered physical habitat. Ideally, impact should be evaluated with the original community as a baseline. In most cases, however, this information is unavailable. (Cassar-FRC)

EFFECTS OF SURFACE MINING ON WATER QUALITY IN A SMALL WATERSHED, SULLIVAN COUNTY, INDIANA,
Geological Survey, Indianapolis, IN. Water Resources Div.
J. G. Peters.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $8.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-543, June 1981. 61 p, 12 Fig, 15 Tab, 50 Ref.

Descriptors: *Water quality, *Coal mining, *Water pollution effects, *Acid mine drainage, Small watersheds, Geology, Strip mines, Hydrogen ion concentration, Dissolved solids, Alkalinity, Cation exchange, Heavy metals, Suspended solids, Sediment transport, Settling basins, Chemical stratification, Thermal stratification, Profiles, Algae, *Indiana, Sullivan County, Spencer Creek, South Lake.

The water quality in an unnamed tributary to Spencer Creek upstream and downstream from a surface mine and in South Lake adjacent to the mine were monitored during a 5-year study (1975-79) in the 1,210-acre watershed of the tributary. Compared with the background values, pH and concentrations of all major dissolved ions and dissolved, suspended, and streambed metals generally increased in Spencer Creek tributary downstream from the mine. Median dissolved-sodium and sulfate concentrations increased as much as eighteenfold and fourteenfold, respectively, and median dissolved-manganese and suspended aluminum concentrations increased as much as sevenfold and more than twofold. Concentrations of suspended metals decreased more than 50% after installation of sediment ponds by the mine operator. During high streamflow, concentrations of major ions at background and at mined sites on Spencer Creek tributary decreased, but dissolved- and suspended-metal concentrations increased downstream from the mine. South Lake exhibited seasonal stratification and mixing characteristics of other lakes at a similar latitude. However, the bottom 3 feet of the water column demonstrated persistent chemical stratification. Phytoplankton populations of the lake varied seasonally, and the population density patterns resembled those in other lakes at latitudes similar to that of South Lake. (USGS)

Descriptors: *Benthos, *Thermal stress, *Nuclear reactors, Nuclear powerplants, Powerplants, Temperature effects, Thermal water, Heated water, *Water pollution effects, *Thermal pollution, Waste heat.

Possible effects of thermal effluents from a nuclear production reactor and other environmental characteristics such as season and plot locality on predator-prey interactions were examined in the littoral zone of a soft-bottom reservoir near Aiken, South Carolina. Thirty-six predator (fish and turtle) exclusion cases were placed in shallow water at six locations along a thermal gradient in Par Pond, a 1100-ha cooling reservoir on the Savannah River Plant. Cages were in place during three, 3-mo test periods beginning in September of 1977. Relations between predator treatment and community response, such as changes in density and taxon richness, were generally unaffected by plot locality, temperature fluctuations from thermal effluent, or seasonal changes. When data from caged and control plots were pooled, however, both location and water temperature individually had direct impacts on the benthic community. (Baker-FRC)

5D. Waste Treatment Processes

WATER-RELATED ENVIRONMENTAL CONTROL REQUIREMENTS AT MUNICIPAL SOLID WASTE-TO-ENERGY CONVERSION FACILITIES,
Iowa State Univ., Ames.
J. C. Young, and L. D. Johnson.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0116, Price codes: A10 in paper copy, A01 in microfiche. Dept. of Energy Report DOE/EV-0116, Sept, 1980. 208 p, 62 Fig, 33 Tab, 46 Ref, Append.

Descriptors: *Waste disposal, *Municipal wastes, *Wastewater treatment, *Water use, Water conservation, Land disposal, Solid wastes, Fuel, Water pollution control, Cost analysis, Energy sources, Recycling, Water reuse.

A study was initiated to evaluate water use and wastewater production at municipal solid waste-to-energy conversion systems, to identify water pollution control technology requirements, and to identify water-related limitations to their design and commercialization. In many designs, water use can be reduced considerably and production of wastewaters often can be eliminated by using water for multiple purposes within a facility. Wastewater associated with waste processing and storage at mass-burning and at dry-process refuse-derived fuel (rdf) facilities usually are produced infrequently and in small quantities, or are essentially uncontaminated. The major point of wastewater production is associated with ash quenching or sluicing and disposal in landfills or ashponds. All water-related environmental concerns associated with these facilities can be satisfied by using available wastewater treatment technology, improved water use management and accepted landfilling practices. Developers of the wet-pulping process have stated that there will be no wastewater discharge from the processing facilities. Wastewaters produced by pyrolysis create the greatest potential for causing adverse environmental impacts because of their high organic content and the type of organic materials present. While satisfactory wastewater treatment can be accomplished, the associated costs may impact heavily upon commercial viability. (Moore-SRC)

ABSORPTION OF RADIUM AND THORIUM FROM NEW MEXICO URANIUM MILL TAILING SOLUTIONS,
Bureau of Mines, Salt Lake City, UT. Salt Lake City Research Center.
H. R. Beard, H. B. Salisbury, and M. B. Shirts.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-147431, Price codes: A02 in paper copy, A01 in microfiche. Report of Investigations 8463, 1980. 17 p, 1 Fig, 5 Tab, 8 Ref, Append.

Descriptors: *Radium, *Thorium, *Radioactive waste disposal, *Mine wastes, *Absorption, Wastewater treatment, Industrial wastes, Uranium, Desorption.

When uranium ore is processed, up to 5% of the radium is taken into solution. Most of this soluble radium passes through the uranium recovery operations to the tailing disposal system. Although the actual weight of radium and other soluble radionuclides is very small, the concentrations in the tailing pond solutions generally are far above the permissible levels. Tailing and soil samples from New Mexico were evaluated for their potential to absorb radium and thorium from tailing liquors. Absorption ranged from 0 to 97% from radium and 0 to 60% from thorium. Essentially all of the New Mexico samples absorbed some radium from the tailing solutions, but the thorium absorption was nil in most cases. Batch desorption tests using relatively dilute ammonium and sodium salt solutions showed desorptions ranging from essentially 0 to 75%. Soils, clays, and other materials can absorb large amounts of radium from uranium tailing solutions, but it has not been possible to relate the absorption to specific chemical or physical characteristics. An alpha spectrometric method was used to determine the radium and thorium concentrations in the solutions and solids. (Moore-SRC)

DEWATERING OF INDUSTRIAL CLAY WASTES,
Bureau of Mines, University, AL. Tuscaloosa Research Center.
A. G. Smelley, B. J. Scheiner, and J. R. Zatko.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-179954, Price codes: A02 in paper copy, A01 in microfiche. Bureau of Mines Report of Investigations 8498, 1980. 15 p, 3 Fig, 11 Tab, 6 Ref.

Descriptors: *Clays, *Industrial wastes, *Dewatering, *Flocculation, Wastewater treatment, Polymers, Solids, Slurries, Coal, Potash, Phosphates, Uranium, Talc, Titanium.

As a part of research conducted in its mission to effect pollution abatement, the Bureau of Mines is developing a dewatering technique that allows for disposal of clay wastes, for reuse of water now lost with clays, and for reclamation of mined land. The technique utilizes a high-molecular-weight nonionic polyethylene oxide polymer (PEO) that has the ability to flocculate and dewater materials containing clay wastes. In laboratory experiments, coal-clay waste, potash-clay brine slurry, phosphatic clay waste, uranium tailings, and talc tailings were successfully consolidated. Coal-clay waste was consolidated from 3.6 to 57% solids; potash-clay brine slurry was consolidated from 3.8 to 35%; phosphatic clay waste from 15.6 to 49%; uranium tailings from 15.4 to 67%; tailings from talc production from 9.7 to 53%; and an acidic titanium dioxide slurry from 1.68 to 30%. In most cases PEO with a molecular weight of 8 million was superior to a 5 million molecular weight polymer. (Brambley-SRC)
W82-00041

TREATMENT OF FLORIDA SURFACE WATERS FOR USE IN PHOSPHATE BENEFICIATION,
Bureau of Mines, University, AL. Tuscaloosa Research Center.
D. A. Stanley, B. J. Scheiner, and P. Brown.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-232407, Price codes: A02 in paper copy, A01 in microfiche. Bureau of Mines Report of Investigations 8535, 1981. 13 p, 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Organic matter, *Surface water, *Industrial water, *Wastewater treatment, Flocculation, Filtration, Water quality, Impaired water use, Phosphates, *Phosphate mining, *Recycling, Water reuse, Florida.

In response to competition for water by other users, the phosphate mining industry has reduced its total water use by recycling, but lost water is generally replaced by deep well pumping from the Floridian aquifer. A potential alternative source of supply is surface water; however, humic products in central Florida surface waters interfere with the flotation beneficiation process. Laboratory-scale experiments were conducted to determine whether or not surface waters with a high organic content could be purified sufficiently to be used to replace the high-quality deep well water. Water samples were obtained from Oak Creek and Horse Creek located in Polk County. The color of the waters was 300 Pt-Co units. The water samples were flocculated with a cationic polyethylenimine polymer, and processed in a sand filter. This treatment removed most of the organic materials from the water. Untreated surface water, treated surface water, and distilled water were used to compare the flotation response of the acid insolubles in an amine flotation circuit. Surface water treated with PEI-1000 was shown to be as effective as distilled water for the acid-insoluble-flotation step. Flocculation and filtration can therefore produce water suitable for amine flotation of quartz, which would permit substitution of surface water for deep well water. (Moore-SRC)
W82-00048

DEWATERING FLORIDA PHOSPHATIC CLAY WASTES WITH MOVING SCREENS,
Bureau of Mines, University, AL. Tuscaloosa Research Center.
L. W. Brandt.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-104373, Price codes: A02 in paper copy, A01 in microfiche. Bureau of Mines Report of Investigations 8529, 1981. 19 p, 8 Fig, 4 Tab, 8 Ref.

Descriptors: *Dewatering, *Clays, *Industrial wastewater, *Mineral industry, Gels, Sedimentation, Slurries, Wastewater treatment, Attapulgite, Phosphates, Phosphate mining, Florida.

Phosphatic clay wastes from beneficiation plants are stored in large dammed areas to allow natural settling. Because they are colloidal suspensions, these wastes settle very slowly, only to about 20% solids in many years. A novel technique to effectively dewater phosphatic clay wastes was developed. The solids contained in the clay waste slurry are slowly compressed by moving wire mesh screens through the system. Slow compression rates gave best results, and the mesh size of the screen used was of secondary importance to the rate of compression. It is believed that the moving screens distort the gel structure of the phosphatic clay system and cause the release of water. Samples of 18 clay wastes, including a high-grade attapulgite from beneficiation plants of the Florida phosphate field, were studied using the method. Typical samples were concentrated from initial solids of 4.7 and 11.9% to 16.8 and 25.2%, respectively, in 3 1/2 days. The high-grade attapulgite sample was dewatered from 2.7% solids to 13% solids in the same period. In general, clay wastes with poor natural settling behavior give higher final solids by moving screen compaction than those that are better natural settlers. The work demonstrated that a different mechanism was operating in compaction than in natural settling because the high attapulgite samples responded well to screen compaction. (Moore-SRC)

LAND RESTORATION FOLLOWING OIL-WELL DRILLING,
V. L. Dover, Jr.
U.S. Patent No. 4,234,421, 7 p, 1 Fig, 7 Tab, 11 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1106, November 18, 1980.

Descriptors: *Patents, *Waste treatment, *Separation techniques, Chemical reactions, Water pollution sources, Waste disposal, *Land reclamation, *Oil fields, *Drilling fluids, Water reuse, Energy conservation, Water recovery, Drill cuttings.

An admixture of waste (oil-well) drill cuttings, drilling fluid and by-products of rotary drilling are separated into good-quality water and high-density

solids by chemical and mechanical means in original earthen-mud storage and/or reserve pits. The treatment produces two useful benefits: (1) good-quality water (useful for agriculture or for drilling a new well) is recovered, and (2) resulting concentrated solids are of such a high density that the land area occupied by and containing such dewatered solids can be immediately leveled and restored to the same use it had before the well was drilled. The effect is a reduction in energy over the present method of hauling whole mud off by trucks to a commercial waste-disposal site. When environmental considerations do not require restoration of the site and reserve pits are allowed to weather to a point of collapse, this process reduces or eliminates surface pollution of nearby creeks, rivers and ponds by preventing release of drilling-fluid chemicals. It also effects a net reduction in energy by breaking the pollution chains. (Sinha-OEIS)
W82-00057

PROCESS FOR REMOVAL OF MERCURY AND MERCURY COMPOUNDS FROM AQUEOUS SOLUTIONS AND INDUSTRIAL WASTE LIQUORS,
Wacker-Chemie G.m.b.H., Munich (Germany, F. R.). (Assignee).
E. Falbesaner, J. Bichler, and E. Wimmer.
U.S. Patent No. 4,234,422, 4 Fig, 6 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1106, November 18, 1980.

Descriptors: *Patents, *Wastewater treatment, *Water pollution treatment, *Separation techniques, *Industrial wastes, Filtration, *Mercury, Sands, Filters, Mercury removal, Backwashing.

A process removes mercury and mercury compounds from aqueous solutions and, in particular, industrial waste waters, by reduction and filtration. After reduction, the waters are cleared by letting the mercury particles and dirt particles flow into a settling basin. Subsequently, the supernatant aqueous solution from the settling basin is subjected to filtration in a deep filter with a filtering agent having a grain size of 0.02 mm to 2 mm and preferably 0.04 mm to 0.6 mm, whereupon the mercury is returned by reverse rinsing the settling basin from the filter and is separated in the settling basin. (Sinha-OEIS)

ENERGY RECOVERY SYSTEM,
Department of Energy, Washington, DC. (Assignee).
A. S. Moore, and F. H. Verhoff.
U.S. Patent No 4,234,423, 6 p, 1 Fig, 12 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1106, November 18, 1980.

Descriptors: *Patents, *Wastewater treatment, Industrial wastes, Pollutants, Organic wastes, Oxidation, *Chemical oxygen demand, Scrubbers, *Coal gasification plants, Wet air oxidation.

The invention is directed to an improved wet air oxidation system and method for reducing the chemical oxygen demand (COD) of waste water used from scrubbers of coal gasification plants, with this COD reduction being sufficient to effectively eliminate waste water as an environmental pollutant. The improvement of the invention is provided by heating the air used in the oxidation process to a temperature substantially equal to the temperature in the oxidation reactor before compressing or pressurizing the air. The compression of the already hot air further heats the air which is then passed in heat exchange with gaseous products of the oxidation reaction for 'superheating' the gaseous products prior to its use in turbines as the driving fluid. The superheating of the gaseous products significantly minimizes condensation of gaseous products in the turbine so as to provide a substantially greater recovery of mechanical energy from the process. APPARATUS FOR THE PURIFICATION OF OILY EMULSIONS, SOLUTIONS, AND INDUSTRIAL WASTE WATERS,
R. F. Piepho.
U.S. Patent No. 4,234,424, 9 p, 5 Fig, 5 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1107, November 18, 1980.

Descriptors: *Patents, *Wastewater treatment, *Industrial wastes, *Separation techniques, *Oily water, Chemical reactions, Filtration, Filters, Equipment, Oil industry.

The invention relates to an apparatus for the purification of oily emulsions, solutions, industrial waste waters or the like. The apparatus includes a reaction container, at least one discharge connecting piece, an inflow trough and a band filter fitted with a fleece band, a filtrate container arranged under it and a sludge container provided at the discharge end of the band filter. The process for purification by chemical separation includes collecting the oily waste waters, adding a demulsifier if the oil content exceeds 2% and separating, or draining, the oil which floats to the surface. A powdered separating reagent may be mixed into the emulsion with adsorption occurring in a very short period of time. The apparatus can be transported to the site where the contaminated waste waters occur. A further object is to increase overall performance in waste water treatment by providing an apparatus with two treatment chambers so that one may operate while the second is being filled and by also providing that the sludge produced by the apparatus has an elongated drying path. (Sinha-OEIS)

PRESSURIZED OXYGENATION SYSTEM AND METHOD,
FMC Corp., San Jose, CA. (Assignee).
C. C. Pearson.
U.S. Patent No. 4,235,719, 9 p, 2 Fig, 9 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 4, p 1532-1533, November 25, 1980.

Descriptors: *Patents, *Wastewater treatment, Sewage treatment, *Oxygenation, Oxygen, Pressure, Equipment.

A system for performing an oxygenation process within a body of sewage at atmospheric pressure includes an oxygen absorber coupled to an oxygen supply at superatmospheric pressure. A storage vessel has an elongate chamber which is oriented vertically in the system. Pipes and valves are coupled to the upper and lower ends of the chamber so that the chamber is alternately connected with the oxygen absorber and the body of sewage, thereby providing alternate high pressure and low pressure half cycles respectively. Initially, oxygenated liquor at superatmospheric pressure is in the oxygen absorber and the elongated chamber is filled with a quantity of oxygen content liquor at atmospheric pressure. The valves are then operated during the high pressure half cycle to admit oxygenated liquor into the elongate chamber through the lower end and to simultaneously expel liquor and undissolved oxygen from the upper end into the oxygen absorber. The valves are then operated during the low pressure half cycle to reduce the chamber pressure to atmospheric and to admit a quantity of liquor from the body of sewage into the elongate chamber through the top end while simulataneously expelling the oxygenated liquor from the bottom end into the body of sewage. Thus, oxygen which comes out of solution and collected as relatively large bubbles as the pressure in the chamber is reduced to atmospheric pressure, will be retained in the elongate chamber and returned to the oxygen absorber during the next high pressure half cycle. (Sinha-OEIS)

UNDERWATER AERATOR,
Hanshin Engineering Co. Ltd., Osaka (Japan). (Assignee).
R. Nakajima, Y. Takei, S. Kawauchi, and T. Fujita.
U.S. Patent No. 4,235,720, 6 p, 4 Fig, 15 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 4, p 1533, November 25, 1980.

Descriptors: *Patents, *Wastewater treatment, *Water pollution treatment, *Aeration, Equipment, Circulation, Bubbles, Underwater.

An aerator comprises an air diffuser rotor for receiving air and forcing out the air through small perforations formed in its peripheral wall, and an agitator-pump unit placed immediately above the rotor. When the aerator is installed on the bottom of a waste water purifying tank, the agitator-pump unit raises water from the bottom of the tank and produces a circulating flow of water through the interior of the tank, while the air diffuser rotor forces out air bubbles into the circulating flow, whereby an improved areation efficiency can be achieved. (Sinha-OEIS)
W82-00065

HIGH CAPACITY WASTE WATER TREATMENT SYSTEM,
Bauer Bros. Co., Springfield, OH. (Assignee).
M. E. Ginaven.
U.S. Patent No. 4,235,724, 8 p, 5 Fig, 10 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 4, p 1534, November 25, 1980.

Descriptors: *Patents, *Wastewater treatment, *Sewage treatment, *Separation techniques, Flow, Flow control, Screens, Storm water, Quiescent flow.

A system for treatment of waste water received from a sewer system comprises one or more lines of static inclined screen each of which lines is served by a single low lying infeed duct or conduit connected to receive waste water which is discharged from the associated sewage system. Each infeed duct includes longitudinally spaced outlets directed upwardly and vertically to provide a like delivery of waste water embodying solids to each of the screens. Each infeed duct is so designed and interrelated with the line of screen which it serves that each of the screens in the lines is provided with equal volumetric non-turbulent, quiescent flow which is ideal for separating purposes. This is achieved by stepping the cross-sectional area of the infeed duct to achieve a uniform flow velocity at each of its outlets. The system is capable of handling a high volume of turbulent waste water such as is found in a sewage systems infiltrated with large volumes of water due to heavy rains and/or flooding conditions. (Sinha-OEIS)
W82-00066

APPARATUSES FOR THE ANAEROBIC DIGESTION OF NATURAL ORGANIC WASTE,
Hamworthy Engineering Ltd., Fleets Corner (England). (Assignee).
D. L. Hawkes, R. Horton, and D. A. Stafford.
U.S. Patent No. 4,233,155, 6 p, 3 Fig, 13 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 2, p 687, November 11, 1980.

Descriptors: *Patents, *Wastewater treatment, *Organic wastes, Sewage treatment, *Anaerobic digestion, Anaerobic conditions, Separation techniques, Equipment.

An apparatus for the anaerobic digestion of natural organic waste comprises a feed tank, a digester and an outlet tank. There is further provided feed means which feeds waste from the feed tank to the digester at an adjustable continuous rate. A gas pump may be used to recirculate from the top of the digester through a diffuser to the bottom of the digester. A suitable gas pump comprises a container partially filled with liquid so there is a space above the liquid surface and within the container sealed by the liquid from the exterior of the container. The pump is placed in the space. (Sinha-OEIS)

FACULTATIVE LAGOON EFFLUENT POLISHING USING PHASE ISOLATION PONDS,

UNIV OF ILL URBANA CHAMPAIGN

Environmental Protection Systems, Inc., Jackson, MS.
E. C. McGriff.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-205965, Price codes: A08 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-084, July 1981, 3 p, 1 Fig.

Descriptors: *Wastewater lagoons, *Wastewater treatment, *Phase isolation ponds, Effluents, Biochemical oxygen demand, Municipal wastewater, Rainfall, Algae, Suspended solids, *Clinton, *Mississippi.

The performance of phase isolation lagoons was investigated at Clinton, Mississippi, from May 1978 to May 1979. The study system consisted of two facultative lagoons arranged in series followed by two isolation ponds used alternately for final polishing. The isolation ponds were operated on a fill and draw basis with isolation periods varying from 20 to 44 days. It appears that the phase isolation process can, at times, produce an effluent that will meet the National Pollutant Discharge Elimination System (NPDES) limitations for Clinton. However, the process is not consistent in its performance and should not be considered as a final process unit. A significant correlation between the area rainfall and effluent BOD5 and TSS indicates sensitivity of the process to climatic and seasonal conditions. A correlation matrix showed a relationship between the effluent suspended solids, and in situ secchi depth, suspended solids, nitrate nitrogen, and total phosphorus. Microscopic examinations revealed that Chlorella appeared most often in both isolation ponds, with Oscillatoria, Ankistrodesmus, Pediastrum, and Ulothrix dominating to a lesser degree. (Moore-SRC)

WASTEWATER TREATMENT BY ROOTED AQUATIC PLANTS IN SAND AND GRAVEL TRENCHES,
Moulton Niguel Water District, Laguna Niguel, CA.
P. R. Pope.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-213241, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-091, July 1981. 6 p, 3 Fig, 2 Tab.

Descriptors: *Biological wastewater treatment, *Aquatic plants, *Raw wastewater, *Municipal wastewater, Wastewater treatment, Nitrogen removal, Phosphorus removal, Laguna, *California.

A patented process developed by the Max Planck Institute (MPI) of West Germany to treat industrial wastes was evaluated as an energy-efficient method to treat municipal wastewater. The major goal was to achieve effluents meeting the Federal Effluent Standards using this novel biological treatment process that requires a minimal amount of mechanical equipment and manpower for normal operation. The Moulton Niguel Water District of Laguna, California, constructed and operated an earthen trench system using rooted aquatic plants for the treatment of wastewater. Two trenches in series were planted with the reed Phragmites and the bulrush Scirpus, respectively. A 2-month study using conventional secondary effluent as the trench influent showed the system was not effective for removing nitrogen and phosphorus components. An 11-month study demonstrated that raw screened wastewater applied to the trench system at a rate not exceeding 95 cu m/d (25,000 gpd) could be treated to secondary effluent quality. Spatial requirements were about the same as for a septic tank system.

EVALUATION OF THE EFFECTIVENESS OF GRANULAR ACTIVATED CARBON ADSORPTION AND AQUACULTURE FOR REMOVING TOXIC COMPOUNDS FROM TREATED PETROLEUM REFINERY EFFLUENTS,
Robert S. Kerr Environmental Research Lab., Ada, OK.
J. E. Matthews.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-199374, Price codes: A04 in paper copy, A01 in microfiche. Project Summary EPA-600/S2-81-067, July 1981. 4 p, 4 Tab.

Descriptors: *Industrial wastewater, *Oil industry, *Activated carbon, *Adsorption, *Aquaculture, *Wastewater treatment, Biological treatment, Organic compounds, Advanced wastewater treatment, Hydrocarbons, Toxicity.

Activated carbon adsorption isotherms of prepared aqueous solutions of toluene, 2,4-dimethylphenol, naphthalene, benzo(a)pyrene, chrysene, pyrene, acenaphthene, phenanthrene, fluoranthene, and fluorene were determined by laboratory studies to estimate the optimum loading capacity under ideal conditions. Effectiveness of activated carbon and aquaculture for removal of organic compounds from a treated petroleum refinery wastewater was evaluated with a pilot-scale treatment system onsite at a refinery. Activated carbon was shown to be effective in removing selected organic compounds; however, there was a wide variation in the adsorption capacities of the compounds tested. In general, adsorption capacity of activated carbon appears to decrease with an increase in the complexity of the polynuclear aromatic molecule. It would require relatively high dosages of carbon to remove the five-membered aromatic ring compounds. Advanced treatment using activated carbon or aquaculture appears to significantly improve petroleum refinery wastewater with respect to toxicity reduction. A literature review of activated carbon treatment indicated considerable variation in estimates for both capital investments and annual operating costs. (Moore-SRC)

VIRUS REMOVAL IN WASTE STABILIZATION PONDS IN INDIA,
National Environmental Engineering Research Inst., Nagpur (India).
V. C. Rao, S. B. Lakhe, and S. V. Waghmare.
Water Research, Vol 15, No 7, p 773-778, July, 1981. 7 Tab, 19 Ref.

Descriptors: *Viruses, *Stabilization ponds, Ponds, *Wastewater treatment, Ammonia, *India, Biological oxygen demand, Seasonal variation.

Stabilization ponds, a low cost waste treatment method used in India and other tropical developing countries, removed 86-95% of viruses from sewage on a pilot scale and 88-98% on a full scale. In the pilot tests, the percentage of virus removed was not significantly affected by rate of loading (205-472 lb BOD5 per acre per day), percentage of BOD5 removal (50-85%), and season (20-26 degrees C in winter and 30-35 in summer). Three 1-celled ponds of varying depths (3,4 and 5 ft, respectively) removed 66, 89, and 81% of the viruses in winter and 89-98% in fall, summer and rainy seasons. Depths of 3, 4, and 5 feet gave overall (averaging all seasons) removal efficiencies of 86, 95, and 93%, respectively. The anaerobic activity, causing frequent sludge uplift, in turn removed colloidal organics and viruses. Viruses were also removed by adsorption to suspended solids and subsequent settling to the extent of 63%. The free ammonia concentrations of 1.5-22 mg per liter and pH above 8.0 also contributed significantly to virus inactivation. (Cassar-FRC)

MODELING AMMONIUM EXCHANGE AND REGENERATION ON CLINOPTILOLITE,
Minnesota Univ., Minneapolis. Dept. of Civil and Mineral Engineering.
M. Semmens, J. Klieve, D. Schnobrich, and G. W. Tauxe.
Water Research, Vol 15, No 6, p 655-666, June, 1981. 14 Fig, 4 Tab, 6 Ref.

Descriptors: *Ammonium, *Ion exchange, *Computer models, Clinoptilolite, Model studies, *Wastewater treatment, Regeneration, Nitrogen compounds, Design criteria, Ammonium removal.

A computer model is presented to assist in the design of ammonium removal facilities in wastewater treatment plants. This predicts the exchange behavior of natural clinoptilolite, an ammonium selective ion exchanger, during service and regeneration. The regeneration model outputs may be used as inputs for the service model to evaluate the impact of alternative regeneration conditions on ammonium removal performance during service. The isotherms obtained in this study may be used to predict the influence of regeneration strengths between 0.2 and 0.4 M NaCl and ammonium concentrations of 5 to 40 mg per liter in influent wastewaters. (Cassar-FRC)

METHANE PRODUCTION FROM OZONATED PULP MILL EFFLUENT,
Purdue Univ., Lafayette, IN. Lab. of Renewable Resources Engineering.
C. E. Bremmon, M. F. Jurgensen, and J. T. Patton.
Journal of Environmental Quality, Vol 9, No 3, p 412-416, July-September, 1980. 2 Tab, 30 Ref.

Descriptors: *Pulp wastes, *Methane, Energy sources, Pulp and paper industry, Industrial wastes, Industrial plants, White water, Kraft mills, Sulfite liquors, Fermentation, Biodegradation, Anaerobic conditions, Sulfite mills, Sulfite liquors, *Waste treatment, *Secondary productivity.

The potential for producing methane from ozone-degraded spent sulfite liquor (SSL) by anaerobic fermentation was investigated. The ozonated SSL was fed continuously to three anaerobic fermenters for three months as the sole source of carbon and energy. The fermenters were inoculated with anaerobic bacteria obtained from sewage sludge and acclimated for one month in ozonated SSL prior to continuous fermentation. Chemical and biological parameters such as COD, BOD5, total sulfur content, redox potential, pH, fatty acid composition, and methane bacteria populations were monitored to determine changes in the SSL during fermentation. Methane production from ozone-treated SSL averaged 1.7 liters per liter, or 17 ml of methane produced per gram of volatile solids fed. Fatty acids analysis of fermenter effluent indicated a net production of 58 mM per liter of acetate during ozonated SSL fermentation. This acetic acid production shows future potential for further fermentation by protein-producing yeast. Although the rate of conversion of volatile solids to methane in this process was not competitive with domestic or agricultural waste digesters, the study did indicate the potential benefits of ozonating organic wastes for increased methane fermentation yields. (Baker-FRC)

SURVIVAL OF EGGS AND LARVAE OF SWINE NEMATODE PARASITES IN AEROBIC AND ANAEROBIC WASTE TREATMENT SYSTEMS,
Kansas Dept. of Health and Environment, Topeka.
O. G. Marti, C. V. Booram, and O. M. Hale.
Journal of Environmental Quality, Vol 9, No 3, p 401-405, July-September, 1980. 5 Tab, 17 Ref.

Descriptors: *Nematodes, *Waste recovery, Recycling, Waste treatment, Aerobic digestion, Anaerobic conditions, Temperature effects, Parasites.

Eggs and larvae of several genera of swine nematode parasites were studied in two experiments to determine their ability to survive aerobic and anaerobic treatment at two different temperature

levels, 12 and 22 degrees C. Swine feces containing eggs of Ascaris suum, Metastrongylus spp., Oesophagostomum dentatum, Hyostrongylus rubidus, and Strongyloides ransomi were used in both experiments. Treatment system fluids were sampled and examined periodically for parasite eggs and larvae. Cultures of fluids were prepared and examined for larvae after seven days of incubation at 25 degrees C. Ascaris eggs embryonated in 28 days in the 22 degree C aerobic system. Unembryonated Ascaris eggs in the other three treatment systems completed their development when transferred to two percent formalin at 25 degrees C. Metastrongylus eggs survived all treatment systems, but some larvae hatched and died. Oesophagostomum and Hyostrongylus larvae survived well under 12 degree aerobic conditions, but were destroyed in 11 days at 22 degrees C. Eggs of Strongyloides hatched rapidly under aerobic conditions, but survived at least seven days under anaerobic conditions in both experiments. The development of free-living adults of Strongyloides and the survival of third-stage larvae were favored in 22 degree C conditions. Knowledge of the parasite genera present in a swine herd and of the responses of eggs and larvae to different temperatures and treatments is significant for the effective management and safe recycling of waste materials. LEACHATES FROM SOLID WASTE RECOVERY OPERATIONS,
Brice, Petrides, and Associates, Inc., Waterloo, IA.
A. D. Rademaker, and J. C. Young.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY1, p 17-29, May, 1981. 5 Fig, 7 Tab, 5 Ref.

Descriptors: *Wastewater treatment, *Leachates, *Waste recovery, *Wastewater renovation, Leaching, Heavy metals, Biological wastewater treatment, Biological treatment, Percolation, Soil types, Sludge, Pollutant identification, Organic wastes, Solid wastes.

A two phase study was conducted to determine the nature of residues produced at urban waste-to-energy conversion facilities and to evaluate leachates produced from the residues. Leachate samples were collected daily and analyzed weekly to see if heavy metals and organic priority pollutants could be leached in sufficient quantities to pose a potential environmental hazard. The effects of soil on the character of the resulting leachate produced from the selected waste residues were also examined. Bench scale column tests revealed that levels of effluent constituents declined gradually from a peak early in the leaching period to essentially zero at 5-7 weeks. Although no organic priority pollutants were found in ash residues, they were present in sludges from the biological treatment of pyrolysis waste waters. Soil columns were successful in removing most base-neutral extractable organic compounds, but not acidic extractable compounds. Some metallic priority pollutants were also removed upon contact with the soil. More research is required into better techniques for removing compounds from solid residues, the identification of organic priority pollutants, and designing models to describe the leaching of priority pollutants from landfills. (Geiger-FRC)

REFUSE-TO-ENERGY WASTEWATER TREATMENT,
Montgomery (James M.), Inc. Pasadena, CA.
G. P. Treweek.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY1, p 1-16, May, 1981. 4 Fig, 5 Tab, 22 Ref.

Descriptors: *Fuel, *Wastewater treatment, *Wastewater renovation, Incineration, Anaerobic digestion, Biological treatment, Trace metals, Organic wastes, Waste recovery, Waste characteristics, Waste disposal, Wastewater disposal, Pilot plants, Wastewater facilities, Biological wastewater treatment.

A two step procedure consisting of preprocessing and conversion is described for processing wastewater refuse into useable fuel. Preprocessing consists of a series of physical steps to size, classify, and separate the refuse, while conversion is carried out by combustion, pyrolysis, anaerobic digestion, or methanation, depending upon the process used for preparing the municipal solid wastes (MSW). Wastewaters from combustion processes consist mainly of site drainage and wash waters, quench and sluice waters, boiler blowdown, and scrubber effluent. The first three wastewaters may be handled by sanitary sewers. The treatment of scrubber wastewater may involve the removal of trace metals before discharge into sanitary sewers. Pyrolysis of preprocessed MSW results in the production of a gas, an oily or liquid fraction, and a solid char fraction. Wastewaters produced during pyrolysis contain high levels of organic priority pollutants. Anaerobic digestion of MSW is still in the development stage, and a test site at Pompano Beach, Florida anticipates wastewater streams from storage pit drainage and liquid effluent generated from dewatering the digested sludge. Projected treatment facilities and recommended pilot plant studies for the handling of wastes for fuel conversion are described. (Geiger-FRC)

FOAM CONTROL IN AERATION TANKS,
Los Angeles County Sanitation Districts, Whittier, CA.
W. W. Hoffmaster.
Water/Engineering and Management, Vol 128, No 5, p 84, 89, May, 1981. 1 Fig, 2 Tab.

Descriptors: *Foam separation, *Foaming, *Aeration, *Wastewater treatment, Pumps, Sprays, Mechanical equipment, Performance evaluation.

A mechanical foam breaker was tested at an activated sludge wastewater treatment plant. Foam control for aeration tanks in Los Angeles County Sanitation Districts consists of foam sprays and vacuum pumps. Foam sprays are a set of nozzles spaced about 6.5 ft apart. These physically break up the bubbles. Greater control is provided by the vacuum pumps. The pumps suck the foam off the surface of the tanks and thus limit foam production by removing it. During the tests of the rotating brush type breaker, the 37.5 mgd plant, which consisted of 12 aeration tanks, was being operated in a contact stabilization mode. The depth of foam was approximately six to eight in. The unit reduced the foam cover by 223 sq ft in 95 min when the tank was baffled at 32.5 ft. Eighty-four percent of the foam was reduced within 10 minutes. In an unbaffled tank running continuously, the foam splitter maintained a difference of 3.4 ft of uncovered foam. A thin layer of scum was a by-product of the system, but the splitter was much cheaper than a suction device which would eliminate the scum. (Small-FRC)

GREECE WON'T BE LETTING WASTEWATER PROBLEMS SLIDE.
Water and Sewage Works, Vol 127, No 2, p 54, 59, February, 1980.

Descriptors: *Greece, Athens, *Wastewater facilities, Wastewater management, Wastewater treatment, Municipal wastewater.

Several recent events in Greece have led that country to take action in the water pollution field. The first municipal wastewater treatment plant had been built in the central part of the country. Athens, the largest city, with nearly 1 million people in the greater metropolitan area, expects to get underway with a design for its first treatment plant as well. The extremely heavy direct disposal of untreated wastes into offshore waters has severely harmed the fishing industry, on which the country depends heavily. Greece will also need to achieve some level of compliance with the EEC pollution control standards before becoming a full member of the common market. Shortly after World War II, a start was made toward the fine, well-engineered, constantly expanding water system enjoyed in Athens today. Athens receives good quality mountain stock water in plentiful supply; it is subjected to treatment such as coagulation with alum, filtration and chlorination at 7 ppm. (Baker-FRC)
W82-00182

TOTAL ORGANIC HALOGEN AS A PARAMETER FOR THE CHARACTERIZATION OF RECLAIMED WATERS: MEASUREMENT, OCCURRENCE, FORMATION, AND REMOVAL,
Karlsruhe Univ. (Germany, F.R.). Dept. of Water Chemistry.
M. R. Jekel, and P. V. Roberts.
Environmental Science and Technology, Vol 14, No 8, p 970-975, August, 1980. 2 Fig, 5 Tab, 23 Ref.

Descriptors: *Chemical analysis, *Organic compounds, *Reclaimed water, Water use, Water analysis, Measuring instruments, Water pollution control, Drinking water, Halogens.

A method is described for the determination of total organic halogen whereby purgeable and nonpurgeable fractions are measured separately. The detection limits are 0.03 micromol/liter halogen for the purgeable fraction and 1.0 micromol/liter halogen for the nonpurgeable fraction. Precision is 5%. Data are presented from two water-reclamation facilities in California. The treated wastewater (secondary effluent) contains 1.0 to 10 micromol/liter total organic halogen, mostly in the nonpurgeable fraction. The mole ratio of organic halogen to organic carbon is about 0.4 to 1.2%. Nonpurgeable halogenated organics are formed during chlorination. The halogenated compounds are removed in several treatment steps: air stripping is effective in decreasing the concentration of the purgeable fraction; activated-carbon and reverse-osmosis treatment substantially reduce the concentration of the nonpurgeable fraction. The halogenated organics remaining after water reclamation appear to be highly mobile in the groundwater environment. Considering the potential health effects of halogenated organics in drinking water, their removal should be considered a major treatment objective in water reclamation. (Baker-FRC)

ASSIMILATION OF LEMONADE-PROCESSING WASTEWATER BY YEASTS,
New York State Agricultural Experiment Station, Geneva. Dept. of Food Science and Technology.
Y. D. Hang.
Applied and Environmental Microbiology, Vol 39, No 2, p 470-472, February, 1980. 2 Fig, 1 Tab, 11 Ref.

Descriptors: *Wastewater treatment, *Food processing industry, Food-processing wastes, Industrial wastes, *Yeasts, Fungi, Growth, Temperature effects, Acidity, Citric acid, Lemonade processing.

The ability of various yeasts to grow on the waste effluents generated during the processing of lemonade was investigated. Five species of yeasts were examined, but only Candida utilis and Saccharomyces fragilis reduced the BOD by greater than 60%. However, C. utilis settled very slowly. In contrast, S. fragilis settled very rapidly and compacted well, and up to 95% of the yeast solids settled in 15 minutes. For this reason in particular S. fragilis is a more desirable organism for treating lemonade-processing wastewater than C. utilis. S. fragilis competed successfully with the natural biota in the wastewater. There were no marked differences between yeast growth in the autoclaved and unautoclaved waste material. Biochemical changes during fermentation of lemonade-processing wastewater by S. fragilis were determined. The amount of yeast growth approximately paralleled the reduction of BOD in the waste water. Both yeast growth and BOD reduction increased rapidly between 12 and 24 hr and reached maxima in 32 hr. The BOD was reduced from 4,100 to 550 mg/liter, representing a reduction of about 87%. Concurrently, the titratable acidity calculated as citric acid was reduced from 0.52% to 0.012% and the pH was raised from 3.0 to 6.8. S. fragilis was able to grow rapidly over a wide range of temperatures, but the optimum temperature was 30 degrees C. Yeast cells grown at 23

UNIV. OF ILL. URBANA-CHAMPAIGN

to 35 degrees C settled more rapidly than those grown at 40 to 45 degrees C. (Baker-FRC)

REMOVAL AND RECOVERY OF ORGANIC POLLUTANTS FROM THE AQUATIC ENVIRONMENT. 2. REMOVAL AND RECOVERY OF DODECYLBENZENESULFONATE FROM AQUEOUS SOLUTION BY CROSS-LINKED POLY(N-BENZYL-4-VINYLPYRIDINIUM HALIDE),
Kyoto Inst. of Tech. (Japan). Dept. of Chemistry.
N. Kawabata, and T. Morigaki.
Environmental Science and Technology, Vol 14, No 9, p 1089-1093, September, 1980. 4 Fig, 3 Tab, 5 Ref.

Descriptors: *Surfactants, *Resins, *Separation techniques, Organic chemicals, Water pollution control, Adsorbents, Chemical analysis, Anionic surfactants, Dodecylbenzenesulfonate.

An attempt was made to find a new polymeric adsorbent for removal and recovery of sodium dodecylbenzenesulfonate from aqueous solution, which would be more useful than those presently available. Vinylpyridine-divinylbenzene copolymer was used as a polymeric adsorbent for removing DBS from solution. BVP resin in the bromide form was found to have an excellent capacity for removing sodium dodecylbenzenesulfonate from solution. The breakthrough capacity of the resin with less than 1 ppm leakage in the effluent was greater than those observed with commercial anion exchange resins and porous styrene-divinylbenzene resin with no ion exchange functional group. The breakthrough capacity of the BVP resin for DBS adsorption was scarcely affected by the presence of sodium chloride, sodium sulfate, sodium hydroxide, and hydrochloric acid. Elution of the adsorbed DBS from the BVP resin was easily accomplished by a simple treatment with methanolic hydrochloric acid, and the BVP resin was efficiently regenerated as the chloride form. DBS was concentrated into 20-25 wt% solution. The BVP resin in the chloride form showed much the same ability for the adsorption of DBS as the resin in the bromide form. (Baker-FRC)

TREATMENT OF POTATO-PROCESSING WASTE WATER BY AN ANAEROBIC LAGOON-FILTER SYSTEM,
New Brunswick Univ., Fredericton. Dept. of Civil Engineering.
K. C. Lin, and G. J. Brown.
Canadian Journal of Civil Engineering, Vol 7, No 2, p 373-383, 1980. 9 Fig, 2 Tab, 12 Ref.

Descriptors: *Anaerobic lagoons, *Potato wastes, *Food processing industry, *Wastewater treatment, Biological treatment, Lagoons, Filters, Industrial wastewater, Organic loading.

A laboratory-scale model of an anaerobic lagoon followed by anaerobic filtration was very efficient in treating potato processing wastewater. At 20 degrees C, pH 7, and organic loading rates of 0.149, 0.290, and 0.719 kg BOD per cu meter per day, overall removals of COD and suspended solids were 97-98% and 89-97%, respectively. The system operated well under shock loads and under zero loads. Most BOD and suspended solids were removed in the bottom part of the reactors. Optimum load to the lagoon and filter were 0.3 and 0.4 kg BOD per cu meter per day, respectively. pH was maintained at 7 by sodium bicarbonate addition. Sludge buildup was estimated at less than 30% of the lagoon volume in 50 years. Therefore, no sludge removal would be required during the normal design period. Filter clogging is also unlikely. AMES' MUTAGENIC ACTIVITY IN RECYCLED WATER FROM AN ISRAELI WATER RECLAMATION PROJECT,
Johns Hopkins Univ., Baltimore, MD. Dept. of Environmental Health Sciences.
I. Neeman, R. Kroll, A. Mahler, and R. J. Rubin.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 1, p 168-175, January, 1980. 2 Fig, 1 Tab, 16 Ref.

Descriptors: *Recycling, *Water shortage, Water demand, Waste recovery, *Water reuse, Mutagenic activity, Eutrophication, Algae, Wastewater treatment, Carcinogens, *Israel.

A project using eutrophication of sewage water has recently reached the final stages of development at a major facility located south of Tel Aviv, Israel, as part of that country's attempts to reclaim water for human and agricultural uses. Samples of water were collected from two sites in the polishing ponds and from a well located adjacent to the polishing ponds. A non-polar resin was also used to concentrate potential mutagenic materials in the water collected from the polishing pond at the terminal end of the reclamation project. The water samples and the concentrated samples were tested by the Ames assay system. The results reveal the presence in recycled water of low levels of one or more pro-mutagens that require activation by mammalian host factors prior to exhibiting mutagenic activity. The data indicate an absence of a response to unconcentrated water in one tester strain, TA 98, with a positive response in a second strain, TA 100. This coupled with a marked response in both strains to concentrated water extracts. In any case the demonstration of pro-mutagenic activity in various water samples drawn from the recycling facility is clear. The source of this lipophilic pro-mutagenic activity may be directly from industrial or agricultural pollutants or indirectly from microbial action on the myriad organic chemicals present in the oxidation ponds. DESIGN GUIDELINES FOR INCOMPLETELY MIXED OR AEROBIC-ANAEROBIC AERATED LAGOONS,
Nova Scotia Technical Coll., Halifax. Dept. of Civil Engineering.
D. Thirumurthi.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 27-35, 1980. 7 Fig, 3 Tab, 12 Ref.

Descriptors: *Aerated lagoons, *Design criteria, *Aerobic-anaerobic lagoons, Lagoons, *Wastewater treatment, Municipal wastewater, Biological oxygen demand, Organic loading.

Incompletely mixed (aerobic-anaerobic) aerated lagoons can be designed using the Thirumurthi chart, which graphically depicts the Wehner-Wilhelm equation for biological wastewater treatment applications. The biological factors (temperature and wastewater quality) are delineated by a first-order BOD removal coefficient; the physical-hydraulic regimes (mixing pattern and depth-width ratio of lagoon) are represented by a dispersion index. The key to the design is the standard BOD removal coefficient (K), 0.29 per day, for municipal wastewater at a standard temperature of 20 degrees C and organic loading of 20 kg per cu meter per day. Equations for correcting K are provided for actual cases where temperature and organic load differ from the standard. An example design (an aerated lagoon operating in winter) illustrates the design procedure, which should be verified by monitoring the field installation. (Cassar-FRC)

RECOVERY OF INDIGENOUS VIRUSES FROM WASTEWATER SLUDGES, USING A BENTONITE CONCENTRATION PROCEDURE,
Texas Univ. Center for Applied Research and Technology at San Antonio.
C. A. Turk, B. E. Moore, B. P. Sagik, and C. A. Sorber.
Applied and Environmental Microbiology, Vol 40, No 2, p 423-425, August, 1980. 2 Tab, 6 Ref.

Descriptors: *Viruses, *Sludge, *Wastewater treatment, Adsorption, Bentonite, Monitoring.

An adaptation of the bentonite virus concentration procedure to sludges has been developed. The results were obtained by the distilled water elution-bentonite concentration procedure in viral monitoring of liquid sludges undergoing land application at six sites in the United States. Plaque assays for indigenous and seed viruses were performed with confluent monolayers of HeLa cells grown in 100-mm petri plates. Several sludge dispersion techniques, isolating indigenous viruses, were evaluated on primary raw and digested sludges. Bentonite adsorption was accomplished by adding 200 mg bentonite clay per liter, previously expanded by vigorously mixing 1 g of bentonite in 100 ml of distilled water for 1 hr, to the sludge eluate. Calcium chloride was added to give a final concentration of 0.02 M, the pH was adjusted to 6.0 with 1 N HCl, and the sample was mixed for 30 min. Bentonite was recovered by centrifuging the sample at 3,000 x g for 10 min. Levels of enteric viruses detected in field samples ranged from a high value of 215 plaque-forming units per g total suspended solids to a low of 0.2 plaque-forming unit per g. During the monitoring program a total of 64 samples were handled, with 97% yielding viruses by the methodology described. Sample volume reductions expressed as a concentration factor generally exceeded 15. Thus the versatility of the bentonite concentration procedure was demonstrated by the recovery of indigenous virions from primary raw sludges during lab testing and from anaerobically digested and lagooned sludges during field monitoring. THE ALPHA-BETA-GAMMA'S OF WASTEWATER TREATMENT,
Standard Oil Co., Chicago, IL.
J. F. Grutsch.
Environmental Science and Technology, Vol 14, No 3, p 276-281, March, 1980. 5 Fig, 1 Tab, 6 Ref.

Descriptors: *Wastewater treatment, *Activated sludge, Petroleum industry, Organic compounds, Activated carbon, Adsorbents, Carbon, Sludge, Oil refineries, Refinery wastes.

Operation at high sludge age and further enhancement by using high concentrations of powdered activated carbon (PAC) commingled with the activated sludge are two approaches used by the petroleum refining industry to improve the performance of activated sludge processes for the removal of organics from wastewater. The key to operating the activated sludge process (ASP) in the high-sludge-age mode is to recognize the impact of influent solids on the physical properties of the activated sludge, specifically the zeta potential probability distribution. High-sludge-age ASP data indicate that the bacteria use food resources sequentially. First, the cell's energy requirements are met. Then, if pool resources remain, the macromolecules are synthesized. Sequential utilization of

food resources is not unexpected, as the energy resource must exist to construct and locate the macromolecules. In studies where a municipal plant operated at exceptionally high sludge age, the solids equilibrated and the plant operated for 3+ months with no sludge wastage, and about 4 mg/liter solids were lost to the effluent. The hydraulic design of the ASP has a striking impact on which metabolic route of the substrate is used - the biosynthetic fate (alpha) or maintenance energy (beta). (Baker-FRC)

SLUDGE SETTLING HAMPERED BY INDUSTRIAL DISCHARGE,
Williamsport Sanitary Authority, PA.
M. H. Gerardi.
Public Works, Vol 112, No 6, p 95-97, June, 1981. 1 Tab, 11 Ref.

Descriptors: *Sludge conditioning, *Sludge digestion, *Bulking sludge, *Industrial waste, *Biochemical oxygen demand, Sludge, Biodegradation, Digestion, Sludge filters, Organic compounds, Flow discharge, Bacteria, Wastewater, Wastewater treatment, Settleable solids, *Williamsport, Pennsylvania.

In Williamsport, Pennsylvania, poor sludge settling due to gas entrapment by mixed-liquor filamentous organisms was attributed to discharge of a fatty acid derivative waste from food emulsifiers. Filamentous bulking is a major operation nuisance for many activated sludge wastewater treatment plants. The nuisance bacteria possess three outstanding metabolic properties: production of filaments under low dissolved oxygen concentrations, rapid assimilation of organic compounds into lipids, and conversion of nitrites to nitrogen during microbiological denitrification. Treatment measures that have been practiced with some success include the use of return sludge chlorination, decreased mean cell residence time, decreased mixed liquor suspended solids concentration, and return of anaerobic digester supernate. In Williamsport, equalized flow discharge from the manufacturer improved settleability. Pretreatment with ferric chloride and calcium hydroxide followed by dissolved air flotation has been proposed as an alternative control measure. (Titus-FRC)

EFFECTS OF ALPHA, BETA AND THETA FACTOR UPON THE DESIGN, SPECIFICATION AND OPERATION OF AERATION SYSTEMS,
California Univ., Los Angeles. School of Engineering and Applied Science.
M. K. Stenstrom, and R. G. Gilbert.
Water Research, Vol 15, No 6, p 643-654, 1981. 3 Fig, 4 Tab, 80 Ref.

Descriptors: *Aeration, *Design criteria, *Wastewater treatment, Dissolved oxygen, Oxygen transfer, Turbulence, Surfactants, Mass transfer, Bubbles, Alpha factor, Beta factor, Theta factor, Variability, Suspended solids, Temperature, Research priorities, Literature review.

This literature review on alpha, beta, and theta factors in wastewater aeration is the result of work by a subcommittee of a joint EPA-American Society of Civil Engineers group in developing a manual of practice for aerator testing and specifications. The variability of the alpha factor has produced values in the literature from 0.3 to 2.0. It depends on many factors: wastewater quality, mixing, suspended solids concentration, bubble diameter, scale, and especially the method of aeration. An alternative approach to determining the alpha factor, using a synthetic anionic surfactant in the test water, is suggested for further development. The beta factor, or ratio of the saturation dissolved oxygen concentration in clean water, may be measured by the Winkler method if no chemical interferences exist. Otherwise, it should be calculated from a total dissolved solids measurement. Values for the beta factor are about 0.95 for domestic wastewater. Values for the beta factor are about 0.95 for domestic wastewater, 0.77-0.97 for pulp mill wastes. Determination of the beta factor also produces a diversity of values. Temperature correction factors have been reported over the range 1.008 to 1.047 and are dependent on turbulence. A theta factor of 1.024 is suggested for most applications. The many uncertainties involved in the use of these three factors show a need for research on the subject, giving high priority to explanations of the effects of turbulence on alpha and beta factors and analysis of scale-up effects on changing surface tension and oxygen diffusivity. ROLE OF HYDRODYNAMIC FACTORS IN AMMONIA DESORPTION BY DIFFUSED AERATION,
New York State Dept. of Health, Albany. Div. of Lab. and Research.
E. Shpirt.
Water Research, Vol 15, No 6, p 739-743, 1981. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Ammonia, *Aeration, *Hydrodynamics, *Wastewater treatment, Mass transfer, Mathematical equations, Turbulence, Air-water interfaces, Bubbles.

The rate of ammonia removal from water by diffused aeration was described by an equation derived from dimensional analysis and the theory of models. This is relevant to stripping of ammonia from wastewater. The mass transfer process was correlated with hydrodynamic variables reflecting the geometry of the system, the air flow, and the liquid properties (diameter and velocity of the rising bubbles in the water, depth of submersion of the diffusers, and the rate of aeration). Experiments were done at water column levels of 30, 50, and 100 cm and at 3.38, 6.75, 13.50, and 27.0 cu meters per sq meter per hour using tap water at 20 degrees C. Fine bubble aeration was twice as efficient in ammonia removal as coarse bubble aeration. (Cassar-FRC)

THE OPERATION OF A WASTE TREATMENT PLANT. PROCESS DYNAMIC CONSIDERATIONS,
Westvaco Corp., Laurel, MD.
R. P. Wilcox, and J. S. Hudgins.
Tappi, Vol 63, No 2, p 115-117, February, 1980. 5 Fig.

Descriptors: *Pulp and paper industry, *Settleable solids, *Wastewater treatment, Industrial wastewater, Model studies, Kraft mills, Wood wastes, Activated sludge process.

A simple dynamic flow model was developed to predict how materials are propagated through a waste treatment plant. The dynamics were evaluated by treating each of the plant units (primary clarifier, aeration basin, secondary clarifier) as a mixing tank and using Laplace transforms to represent the transfer functions for it. The overall transfer functions are given by the product of the individual transfer functions. Two concentrations were of principal interest: the concentration of the material in the aeration basin (important because of possible inhibiting effects on microorganisms) and the concentration in the secondary clarifier, because of effects the material may have in directly altering settleability. The model was applied to a treatment plant in a southern kraft paper mill. Uses of the model include estimating the maximum entering composition of a material which will not exceed plant capacity. Results apply mainly to nonbiodegradable material such as lignin or inorganics. Substances contributing to BOD are degraded by biological action in an aeration basin and can be included in the model with an additional term. (Cassar-FRC)

LUXURY UPTAKE OF NITROGEN IN FLOCCULATING ALGAL-BACTERIAL SYSTEM,
Government Engineering Coll., Trichur (India). Dept. of Civil Engineering.
K. R. Nambiar, and S. D. Bokil.
Water Research, Vol 15, No 6, p 667-669, 1981. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Nitrogen removal, *Algae, *Bacteria, Biomass, *Wastewater treatment, Nitrogen compounds, Flocculation.

Investigations were conducted, aimed at increasing nutrient removal from fertilizer manufacturing wastewater by a mixed algal-bacterial biomass. Although algae and bacteria nitrogen uptake rates are usually 8-12%, a 16% uptake (luxury uptake) was obtained with added carbon source and added N. In four 3-liter batch reactors fed with 700 mg per liter ammonia-N, 300 mg per liter urea-N, glucose, and phosphate, the flocculating algal-bacterial biomass decreased during the 10-day test, but biomass N remained in the 500 mg per liter range. A C:N:P ratio of 10:10:1 (as against the stoichiometric ratio of 30:10:1) is the optimum for biomass stability and total N removal efficiency. (Cassar-FRC)

SMALL IS ENVIRONMENTALLY ACCEPTABLE . . .,
Water Pollution Research Lab., Stevenage (England).
M. J. D. White.
Water, No 33, p 15-17, July, 1980.

Descriptors: *Wastewater treatment, *Biological wastewater treatment, Anaerobic digestion, Fluidized bed process, Fluidized beds, Dewatering, Separation techniques.

Increasing environmental pressure and space restrictions have led to greater interest in methods for intensifying wastewater treatment processes. Biological degradation and solid/liquid separation comprise the two major types of sewage treatment processes. Both are amenable to intensification options. Biological treatment can be intensified by increasing the number of microorganisms per unit volume. This may be accomplished by increasing the quantity of oxygen supplied during aeration prior to separation in a settlement tank or by using small filter media with a larger surface area rather than traditional filters with mineral media. Biological fluidized beds provide potential for achieving concentrations of microorganisms which are five to ten times greater than those achieved by conventional activated sludge processes. However, subsequent aerobic treatment requires a high rate of oxygen input due to the high concentrations of microorganisms, resulting in high operating costs. The fluidized bed process can be used for anaerobic treatment of industrial wastes containing carbohydrate but not much ammonia or other pollutants. Concentration of sludge prior to anaerobic digestion can reduce the retention period by as much as 65% and results in reduced volume to be treated. The potential for intensification of the separation processes used in sewage treatment appears to be rather limited. Such measures as are feasible are relatively expensive either to construct or to operate. (Carroll-FRC)

PILOT SCALES TESTS ON THE FLOTATION OF ABATTOIR WASTES BY DEEP U TUBES,
Manchester Inst. of Science and Technology (England).
A. D. Wheatley, and S. J. Denham.
Effluent and Water Treatment Journal, Vol 20, No 6, p 274-277, June, 1980. 2 Fig, 8 Tab, 5 Ref.

Descriptors: *Meat processing industry, *Flotation, Animal wastes, Recycling, *Wastewater treatment, Pilot plants.

UNIV. OF ILL. URBANA-CHAMPAIGN

A portable pilot plant was used to test treatment of strong and variable abattoir wastes (up to 3294 mg per liter COD) using the flotation method. The distinguishing feature of the plant was a U-tube shaft. With recycle, total suspended solids removals were over 95%. Without recycle, several problems prevented good results--interference of gas transfer, coagulation by the strong effluent, and inadequate gas precipitation. Corrective measures included increasing residence times in the flotation tank by 2 or 3 times, raising the temperature, adding new particulate matter, and addition of coagulants directly to the shaft. Several experimental procedures--providing gas bubbles as nucleation sites and preaeration prior to entering the shaft--produced no improvement in results. Experiments to selectively remove protein were unsuccessful using sodium hexametaphosphate as a coagulant at low pH, a recycle ratio of 4:1, and a reduced flow rate. (Cassar-FRC)

A REALISTIC ASSESSMENT OF THE EFFECT OF SETTLEMENT ON SEWAGE,
T. Stones.
Effluent and Water Treatment Journal, Vol 20, No 3, p 119, 121, March, 1980. 5 Tab, 4 Ref.

Descriptors: *Chemical oxygen demand, *Flocculation, Biological oxygen demand, Nitrogen compounds, Suspended solids, *Wastewater treatment, Industrial wastewater.

Total oxygen demand (COD plus nitrogenous oxygen demand) is a more realistic measure of the effect of settlement in sewage than previously used methods. Samples of domestic sewage, both natural and sterilized, were allowed to settle for 18 hours. Of the total reduction in oxygen demand, 91.2% was due to carbonaceous matter and 8.8% due to nitrogenous matter. Overall, 30.3% of the reduction arose from biological activity. Settlement resulted in a reduction of 35.8% of the initial COD, which is equivalent to a reduction of 29.3% of the initial TOD; and a reduction of 15.7% of the initial nitrogenous oxygen demand, which is equivalent to 2.8% of the initial TOD. Data for settlement of industrial sewage showed a marked suppression on the proportion of the reduction of the COD from biological activity because of toxic materials in the sewage. (Cassar-FRC)

CHEMISTRY OF SEPTICITY,
Severn-Trent Water Authority, Birmingham (England).
N. Harkness.
Effluent and Water Treatment Journal, Vol 20, No 1, p 16, 18-19, 21, 23, January, 1980. 2 Fig, 9 Ref.

Descriptors: *Septicity, *Hydrogen sulfide, *Anaerobic conditions, *Odors, Sulfur compounds, Chemical reactions, Sulfides, Organic compounds, Sewer systems, Bacteria, Sulfates, Industrial wastes, Domestic wastes, Amines, Amino acids, Organic matter.

Malodors in sewage result from a variety of biochemical reactions taking place in the absence of free or combined oxygen. The most common, hydrogen sulfide, arises under anaerobic conditions from the breakdown of sulfur-containing organic compounds in a reduced state and from sulfate-sulfur. Examples are amino acids, vitamins, taurine, arylsulfate acids, steroid sulfates, and sulfomucopolysaccharides. These compounds may enter a sewer system from domestic sources (1.0-1.5 g S per person per day), potable water, surface and infiltration water, and industrial effluents. Pomeroy's Z formula allows estimation of the likelihood of sulfide formation in gravity sewers, considering BOD, temperature, slope of sewer, sewage flow, and ratio of pipe wall perimeter to surface width of flow. Low pH, high temperature, and turbulent flow enhance hydrogen sulfide liberation into the atmosphere. Molecular H_2S comprises half the soluble sulfide at pH 7 and 15C, increasing with decreasing pH; at 20C the atmospheric equilibrium concentration is 130 ppm for 0.5 mg per liter H_2S in solution. Other malodors possible in sewage are volatile fatty acids, alcohols, ketones, and amines. (Cassar-FRC)
W82-00325

ADVANCED BIOLOGICAL TREATMENT OF TANNERY WASTEWATER,
D. R. Refling, M. G. Biesinger, and L. K. Barber.
Industrial Wastes, Vol 27, No 3, p 16-18, May/June, 1981. 2 Fig, 4 Tab.

Descriptors: *Wastewater treatment, *Tannery wastes, Industrial wastes, Primary wastewater treatment, Oxidation ponds, Advanced wastewater treatment, Aeration, Aerators, Winchester, New Hampshire.

Wastewater from tanneries is a complex mixture of organic and inorganic chemicals. It is high-strength and extremely variable in nature. Nearly all of the wastewater from the A. C. Lawrence Tannery in Winchester, New Hampshire, is discharged from 3 am to 7 pm, with the peak occurring about 11 am. The permit issues for this discharge specified that effluent concentrations should not exceed: suspended solids, 60 mg/l; BOD, 15 mg/l; ammonium-nitrogen, 1.5 mg/l; FOG, 15 mg/l; and chromium, 1.0 mg/l. Treatment at the plant consists of a primary chemical treatment system followed by an advanced biological secondary system. In the primary system the wastewater is dosed with 1,000 mg/liter alum and 800 mg/liter lime. Wastewater pH is controlled between 7.5 and 8.5. Wastewater then flows through a dispersed air device and a vortex coagulation cell and on to an electro-flotation tank where small gas bubbles attach to the floc particles and float them to the tank surface, where they are removed by skimmers. Polyelectrolyte is injected at a dose of 12 mg/liter just prior to flotation. The biological treatment uses an aeration and mixing system called Carrousel, which is essentially a modification of the Pasveer oxidation ditch concept using low-speed surface aerators instead of horizontal rotors. The effluent produced has been determined to be of extremely high quality, with average effluent BOD values of 5 mg/liter in summer and 6 mg/liter in winter. Effluent ammonia nitrogen values are 1 mg/liter in summer and 4 mg/liter in winter. Over 99% of the raw influent BOD was removed, and nitrogen removal efficiencies were 85.2-89.8%. (Baker-FRC)

RECENT DEVELOPMENTS IN WATER POLLUTION CONTROL,
Toronto Univ. (Ontario). Dept. of Civil Engineering.
J. G. Henry.
Canadian Journal of Civil Engineering, Vol 7, No 2, p 264-272, 1980. 40 Ref.

Descriptors: *Wastewater treatment, *Water pollution control, *Ontario, *Canada, Performance evaluation, Process control, Automation, Activated sludge process, Oxygen, Biological treatment, Rotating biological contactors, Deep shaft process, Fluidized bed process, Land application, Physicochemical treatment, Anaerobic digestion, Incineration, Sludge disposal, Sludge dewatering, Dewatering, Research priorities.

This paper examines the current status of municipal wastewater technology in Ontario, Canada, and recent developments in plant performance, secondary treatment, and sludge processing. These are reviewed with respect to limitations and suitability for Canada. Still in a primitive stage are dynamic design, mathematical modeling for unit processes, and automatic process control. Secondary treatment processes which show promise are the oxygen activated sludge process for large plants, fixed film reactors (such as the rotating biological contactor) for small municipalities, the deep shaft process, and the fluidized bed technique. Land treatment and physical-chemical treatments (activated carbon) are considered impractical for Canada. Sludge processing, which accounts for 40% of wastewater treatment costs, presents many problems. Anaerobic digestion is difficult to operate, and land application is severly restricted. Possible answers to sludge problems are incineration, new dewatering devices such as belt filters, and polymeric sludge conditioners. Research and development on water treatment in Canada must increase. (Cassar-FRC)

TEXTILE EFFLUENTS LOSE THEIR COLOR.
Canadian Chemical Processing, Vol 64, No 2, p 75, March, 1980.

Descriptors: *Color removal, *Textile mill wastes, *Activated carbon, Dyes, *Wastewater treatment, Industrial wastewater.

An activated carbon system was installed in the Harding Carpets factory to treat a highly variable effluent containing textile dyes and other chemicals. A 14.2 cu m holding tank equalizes the waste load. Each carbon bed is 0.9 m in diameter and 3.2 m long and can handle 0.19 cu m per hour of effluent. The entire system, with a 326 cu m per day capacity, removes 95.4% of the color. Significant reductions in total organic carbon, chemical oxygen demand, and biological oxygen demand of the effluent are effected. (Cassar-FRC)

AVOIDING AN ENVIRONMENTAL HANGOVER.
Canadian Chemical Processing, Vol 64, No 2, p 29-30, March, 1980.

Descriptors: *Brewery industry, *Aerated lagoons, Lagoons, *Wastewater treatment, Industrial wastewater, Food processing industry.

Brewery wastes at Molson's Barrie, Ontario, plant are treated on site before release into the municipal treatment system. The plant generates 0.5 to 1 million gal per day of effluent with BOD of 1500-2000 ppm. The wastes are treated in two 2 million gallon lagoons equipped with conventional paddle surface aerators and a Penberthy aerator with a Venturi system. Effluent from the lagoons passes through two clarifiers. Sludge is collected, dewatered to 14% solids concentration, and disposed at a municipal site. Treated effluent is discharged to the municipal system at less than 300 ppm BOD and 350 ppm suspended solids. (Cassar-FRC)
W82-00344

RAPID GROWTH FORECAST FOR PEROXIDE.
Canadian Chemical Processing, Vol 64, No 1, p 21-22, February 6, 1980.

Descriptors: *Hydrogen peroxide, *Hydrogen sulfide, Oxidation, Odor control, *Wastewater treatment, Sludge conditioning.

The United States currently uses 20,000 tons per year of hydrogen peroxide for industrial or municipal wastewater and water treatment. Hydrogen peroxide is primarily a pretreatment agent, degrading many toxic materials (phenolics, refractory organics, cyanide, sulfur compounds, etc.) before the

biological oxidation step. It is also useful as a source of supplemental oxygen during spills, aerator outages, or excess organic loading, and as a sludge conditioner. Hydrogen sulfide can be controlled with hydrogen peroxide without the corrosion and toxicity problems common to carbon adsorption or chlorination. (Cassar-FRC)

FINAL ENVIRONMENTAL IMPACT STATEMENT FOR WASTEWATER TREATMENT FACILITIES; CITY OF OLATHE, JOHNSON COUNTY, KANSAS.
Environmental Protection Agency, Kansas City, MO. Region VII.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-243131, Price codes: A21 in paper copy, A01 in microfiche.
Report EPA-907/9-81-002a, March, 1981. 484 p, 21 Fig, 27 Tab, 118 Ref, 7 Append.

Descriptors: *Environmental Impact Statement, *Olathe, Kansas, *Wastewater treatment, *Wastewater facilities, *Sewer systems, Environmental effects, Sewage districts, Economic aspects, Environmental protection.

This Final Environmental Impact Statement examined 11 alternatives for providing sewerage facilities for the Upper and Little Cedar Creek basins in and near the City of Olathe, Johnson County, Kansas. All alternatives were also intended to relieve existing overloading at Olathe's Harold Street treatment plant. Based on a comparative analysis of both monetary and nonmonetary impacts of the alternatives a preferred project has been selected. It consists of a 2 mgd wastewater treatment plant with a gravity interceptor, one major lift station, a force main and attached flow equalization basins. The gravity interceptor is generally aligned with Little Cedar Creek. The major lift station would pump around the east side of Ernie Miller Park. Recommendations are made for measures to reduce adverse effects of the project. The EPA intends to fund only a limited portion of the originally proposed project. (Brambley-SRC)
W82-00357

FINAL ENVIRONMENTAL IMPACT STATEMENT; BEMIDJI WASTEWATER TREATMENT SYSTEM, BELTRAMI COUNTY, MINNESOTA.
Environmental Protection Agency, Chicago, IL. Region V.
Report, May, 1981. 144 p, 11 Fig, 17 Tab, 106 Ref, Append.

Descriptors: *Environmental Impact Statement, *Bemidji, Minnesota, *Wastewater treatment, *Wastewater facilities, Lakes, Eutrophication, Cost analysis, Water quality, Waste disposal, Land disposal, Social aspects, Tertiary wastewater treatment, Water pollution control, Phosphorus removal.

The effluent discharged from the wastewater treatment plant at Bemidji significantly affects the quality of the culturally and economically important lakes on the Upper Mississippi River downstream from the outfall sewer (Lakes Bemidji, Wolf, Andrusia, and Cass). A permanent solution to the wastewater disposal problem has been sought for more than 12 years, primarily because of the continued search for a means to eliminate a surface water discharge. Numerous land application search efforts have been conducted, and numerous geotechnical investigations and engineering reports have been completed during the past ten years. This Environmental Impact Statement addresses this long alternatives development process. At this time it appears that the only technically feasible, environmentally and socially acceptable, and cost-effective solution to the problem is the construction of a new tertiary wastewater treatment plant at the site of the existing plant in Bemidji with discharge to the Mississippi River channel to Lake Bemidji. It also appears that an effluent phosphorus concentration limitation of 0.3 mg/l (the most practical treatment) will protect Lake Bemidji from accelerated eutrophication and may contribute to improved water quality in the downstream Upper Mississippi River Chain of Lakes. (Brambley-SRC)
W82-00358

FINAL ENVIRONMENTAL IMPACT STATEMENT; WASTEWATER TREATMENT FACILITIES, SOUTH SHORE LAKE TAHOE BASIN.
Environmental Protection Agency, San Francisco, CA. Region IX.
Report, May, 1981. 217 p, 6 Fig, 15 Tab, 10 Ref.

Descriptors: *Environmental Impact Statement, *Lake Tahoe, California, *Wastewater treatment, *Wastewater facilities, Environmental effects, Social aspects, Secondary wastewater treatment, Irrigation water, Agriculture, Growth rates.

This Final Environmental Impact Statement on the wastewater treatment programs proposed by the South Tahoe Public Utility District and the Douglas County Sewer Improvement District No. 1, contains EPA's recommendations, and revisions and additions to the Draft Environmental Impact Statement. Based on the impact analysis of various growth scenarios and commitments to mitigate primary and secondary adverse impacts, EPA recommends for South Tahoe Public Utility District a 7.5 mgd maximum daily flow wastewater treatment plant which produces secondary treated and filtered effluent for agricultural irrigation in Alpine County, California. Possible plant expansion is contingent upon approval by various local and regulatory agencies and adequate performance under the mitigation program. The environmental parameters considered were water quality, biology, noise and air quality, and visual resources. The social parameters considered include land use, housing, transportation, recreation, public services/fiscal concerns, utilities, and cultural resources. The final environmental impact statement for Douglas County Sewer Improvement District No. 1 has been postponed because of lack of progress in developing a mitigation program. (Brambley-SRC)

FINAL ENVIRONMENTAL IMPACT STATEMENT; REHABILITATION OF WASTEWATER FACILITIES, STREATOR, ILLINOIS.
Environmental Protection Agency, Chicago, IL. Region V.
Report, February 1981. 283 p, 11 Fig, 19 Tab, 101 Ref, 4 Append.

Descriptors: *Environmental Impact Statement, *Streator, *Illinois, *Wastewater treatment, *Wastewater facilities, Nitrification, Chlorination, Combined sewers, Effluents, Pit recharge, Water pollution control, Water quality, Pollution load, Leachates.

A Facilities Plan was developed for Streator, Illinois, which recommended substantial upgrading and expansion of the existing system, with separation of the existing combined sewer system, and treatment facilities which would reduce discharges to the Vermilion River. The Final Environmental Impact Statement proposes action on a reduced scale. The three major interceptor sewers in the combined sewer system would be replaced. The treatment plant would be upgraded to include nitrification and chlorination, to obtain effluent levels of 10 mg/l BOD5 and 12 mg/l suspended solids. Combined sewer flows in excess of the plant's capacity would receive primary treatment and chlorination prior to discharge to the river. The mines beneath Streator would be recharged with wastewater and stormwater to maintain present water levels. The proposed action would reduce substantially the pollutant loads to the Vermilion River, so water quality downstream should be improved, especially at low flow periods. Pollutant loads to the mines would be reduced, thus reducing leachate from them. Before any further action is taken it is necessary to determine the feasibility of the less stringent effluent levels, the recharge to the mines, and the sewer rehabilitation; the level of treatment under these conditions; and the most appropriate financing. (Brambley-SRC)
W82-00361

FINAL ENVIRONMENTAL IMPACT STATEMENT; ALTERNATIVE WASTEWATER TREATMENT SYSTEMS FOR RURAL LAKE PROJECTS; CASE STUDY NO. 1: CRYSTAL LAKE AREA SEWAGE DISPOSAL AUTHORITY, BENZIE COUNTY, MICHIGAN.
Environmental Protection Agency, Chicago, IL. Region V.
Report, July 1980. 169 p, 7 Fig, 3 Tab, 7 Append.

Descriptors: *Environmental Impact Statement, *Crystal Lake, Michigan, *Wastewater facilities, *Wastewater treatment, *Water pollution control, Rural areas, Groundwater movement, Septic wastewater, Leachates, Pollution load, Phosphorus, Sewer systems, Case studies.

A Facilities Plan for the Crystal Lake area, which proposed a centralized collection and treatment system for the area, was followed by a Draft Environmental Impact Statement (DEIS), which recommended a Limited Action Alternative. Additional studies were conducted on groundwater flow patterns, septic leachate in Cold Creek, and aquatic productivity in effluent plumes and administrative procedures were clarified. The new studies generally confirmed the earlier ones. Groundwater flow patterns were clarified; under extreme conditions septic tank systems might contribute 6.7% of the lake phosphorus loads projected in the DEIS; and almost all of the dry-weather nutrient load was coming from a small tributary of Cold Creek. The recommended action is essentially that which was recommended in the DEIS, as follows: construction of connecting sewers and a new 0.33 mgd rotating biological contractor plant for Frankfort and Elberta; evaluation surveys and rehabilitation of their existing sewer systems; design and implementation of a small waste flow district for the remainder of the study area; site-specific environmental and engineering analyses of existing systems in the unsewered areas; repair and replacement of on-site systems as required; and cluster systems or other off-site treatment for portions of the shoreline. (Brambley-SRC)
W82-00362

FINAL ENVIRONMENTAL IMPACT STATEMENT; ALTERNATIVE WASTEWATER TREATMENT SYSTEMS FOR RURAL LAKE PROJECTS; CASE STUDY NO. 2: THE GREEN LAKE SANITARY SEWER AND WASTE DISTRICT, KANDIYOHI COUNTY, MINNESOTA.
Environmental Protection Agency, Chicago, IL. Region V.
Report, December 1980. 165 p, 9 Fig, 6 Tab, 4 Append.

Descriptors: *Environmental Impact Statement, *Green Lake, Minnesota, *Wastewater treatment, *Wastewater facilities, *Sewer systems, Cost analysis, Water pollution sources, Groundwater, Water pollution control, Trophic level.

In response to a Facilities Plan for the Green Lake area which proposed a centralized wastewater collection and treatment system, the EPA prepared a Draft Environmental Impact Statement, which proposed alternatives. The centralized collection and treatment system is neither needed nor cost-effective, and the elimination of on-site wastewater system on the shorelines of Nest Lake and Green Lake will not change the trophic status of the lakes. Nonpoint sources are the larger source of nutrients to Nest Lake, and this load subsequently enters Green Lake. The wastewater treatment needs can be met by use of on-site systems, including new and upgraded systems, and by provision of decentralized off-site systems (cluster systems). To ensure reliability of these systems the sites must be chosen carefully; the natural assimilative capacity of local soil and groundwater resources must be considered; and adequate community supervision must be provided. Spicer and New London will continue to use their existing collection systems with final treatment facilities to be determined, while the shorelines of Nest and Green Lakes will continue to be served by on-site systems. UNIVERSITY OF ILLINOIS URBANA-CHAMPAIGN

FINAL ENVIRONMENTAL IMPACT STATEMENT; ALTERNATIVE WASTEWATER TREATMENT SYSTEMS FOR RURAL LAKE PROJECTS; CASE STUDY NO. 3: SPRINGVALE-BEAR CREEK SEWAGE DISPOSAL AUTHORITY, EMMET COUNTY, MICHIGAN.
Environmental Protection Agency, Chicago, IL. Region V.
Report, December 1980. 133 p, 6 Fig, 3 Tab, 9 Ref, 6 Append.

Descriptors: *Environmental Impact Statement, *Springvale - Bear Creek, Michigan, *Wastewater treatment, *Wastewater facilities, Water pollution control, Sewer systems, Septic tanks, Leachates, Eutrophication, Water quality.

Essentially the same action is recommended as in the Draft Statement, prepared in response to a Facilities Plan which called for a sewage collection system around Crooked Lake and Pickerel Lake with conveyance to a central wastewater treatment plant at Petoskey. There are localized shoreline water quality problems, so a Limited Action plan is recommended. The plan proposes the design and implementation of a small waste flows district; site-specific environmental and engineering analyses of existing on-site systems; repair and replacement of on-site systems as required; and cluster systems or other off-site treatment for Ellsworth Point and Botsford Landing. The site analyses should start with Ellsworth Point, Botsford Landing, and those individual systems that were found to be malfunctioning and a source of septic leachate plumes and high densities of Cladophora in the lakes. (Brambley-SRC)
W82-00364

FINAL ENVIRONMENTAL IMPACT STATEMENT; ALTERNATIVE WASTEWATER TREATMENT SYSTEMS FOR RURAL LAKE PROJECTS; CASE STUDY NO. 4: STEUBEN LAKES REGIONAL WASTE DISTRICT, STEUBEN COUNTY, INDIANA.
Environmental Protection Agency, Chicago, IL. Region V.
Report, January 1981. 157 p, 5 Fig, 5 Tab, 7 Append.

Descriptors: *Environmental Impact Statement, *Steuben Lakes, Indiana, *Wastewater treatment, *Wastewater facilities, *Sewer systems, Septic tanks, Cost analysis, Water pollution sources, Leachates, Water quality, Population dynamics, Case studies.

A Facilities Plan proposed a centralized collection and treatment systems for the communities in the Steuben Lakes area. Because of the cost, the uncertainty of the water quality improvements, and the potential for induced growth, the EPA conducted studies for a Draft Environmental Impact Statement. These studies showed that a few on-site treatment systems were having an impact on water quality although many did not comply with the Steuben County Sanitary Code. A Limited Action Alternative was selected which included decentralized systems for the entire area, and a program to replace and rehabilitate on-lot systems. This alternative will constrain future population growth, and result in development patterns that are more scattered and at a lower density than that which could be accommodated by a centralized treatment plant. This alternative will not incur a severe financial burden on most of the residents. (Brambley-SRC)
W82-00365

FINAL ENVIRONMENTAL IMPACT STATEMENT; ALTERNATIVE WASTEWATER TREATMENT SYSTEMS FOR RURAL LAKE PROJECTS; CASE STUDY NO. 5: OTTER TAIL COUNTY BOARD OF COMMISSIONERS, OTTER TAIL COUNTY, MINNESOTA.
Environmental Protection Agency, Chicago, IL. Region V.
Report, November 1980. 202 p, 8 Fig, 4 Tab, 8 Append.

Descriptors: *Environmental Impact Statement, *Otter Tail County, Minnesota, *Wastewater treatment, *Wastewater facilities, *Sewer systems, Septic tanks, Cesspools, Groundwater level, Groundwater pollution, Leachates, Water quality control, Water pollution sources, Coliforms, Case studies.

A Facilities Plan for centralized sewage collection and treatment for Otter Tail County, Minnesota, was rejected in the Draft Environmental Impact Statement (DEIS) because of its cost, uncertainty of water quality improvements, and potential for population growth. Subsequent groundwater hydrology and septic leachate surveys, and analyses of soils, groundwater and aquatic plants led to the Modified Limited Action Alternative. In this plan greywater/blackwater separation will only be used in individual dwellings where it will provide benefits; all cesspools will be replaced with on-site systems; holding tanks will be converted to receive only waste from very low flow toilets; all defective or undersized septic tanks will be replaced; dosed mound systems will be used where high groundwater prevents use of soil absorption systems; and half of the resort units will be served by cluster systems. This plan offers a low-cost solution to the wastewater problems of Otter Tail County - soil, lot size, and groundwater table conditions which make on-site treatment inadequate, high coliform counts in Otter Tail Lake, and high groundwater nitrate concentrations. LIMESTONE-LIME TREATMENT OF ACID MINE DRAINAGE - FULL SCALE,
Peabody Coal Co., St. Louis, MO.
D. G. McDonald, and A. F. Grandt.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-172645, Price codes: A10 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-033, June 1981. 3 p, 1 Fig, 1 Tab.

Descriptors: *Acid mine drainage, *Wastewater treatment, *Chemical treatment, *Neutralization, *Lime, Limestone, Cost analysis, Sludge solids, Settleable solids, Sedimentation, Mine wastes.

A full-scale treatment plant was investigated to determine the most economical treatment of large volumes of highly acidic mine drainage and to characterize sludges from treatment processes as to settling behavior and solids content. Acid mine drainage was neutralized to pH 7.0 with a combination of limestone and hydrated lime, or with hydrated lime alone. The most economical treatment method was achieved through a combination of lime treatment on one line and limestone treatment on a second line, with recirculation on both lines. Both lime and lime-limestone treatment processes produced good settling behavior, with most of the sludges settling within one hour. Limestone treatment produced denser sludges with a higher solids content at pH levels above 4.5 than did the lime treatment. (Brambley-SRC)

PHYSICAL/CHEMICAL TREATMENT OF BLAST FURNACE WASTEWATERS USING MOBILE PILOT UNITS,
Rexnord, Inc., Milwaukee, WI.
R. Osantowski, A. Geinopolos, J. Kane, and G. Rollinger.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-159386, Price codes: A15 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-80-107, May 1981. 4 p, 3 Fig, 5 Ref.

Descriptors: *Wastewater treatment, *Pilot plants, *Steel industry, *Industrial wastes, Chlorination, Ozonation, Reverse osmosis, Cost analysis, Water quality, Standards, Effluents, Metals, Organic compounds, Blast furnace wastewater.

This project was initiated to provide an evaluation of the effectiveness of existing treatment technology for upgrading steel mill wastewaters to Best Available Technology (BAT) Economically Achievable limits for Blast Furnace Category scrubber wastewaters. The wastewater tested was a blast furnace effluent from an operating steel mill treatment system that met 1977 Effluent Guidelines for Best Practical Control Technology (BPT) Currently Available. This wastewater contained residual concentrations of suspended solids, BOD, oils and greases, phenols, cyanides, fluorides, ammonia compounds, sulfides, and dissolved solids. The in-depth pilot plant study was performed using mobile facilities designed especially for treating steel plant wastes. Treatment processes evaluated during the study included: alkaline chlorination, chemical treatment, dual media filtration, magnetic filtration, reverse osmosis, ozonation and activated carbon. Alkaline chlorination, ozonation, and reverse osmosis were all effective at reducing metals to <10 microgram/l except for zinc and selenium, and organics to <10 microgram/l with the exception of bis(2 ethylhexyl)phthalate. Alkaline chlorination was the least-cost alternative, whereas ozonation required least space. (Brambley-SRC)
W82-00378

HIGH-LEVEL OZONE DISINFECTION OF MUNICIPAL WASTEWATER EFFLUENTS,
Metcalf and Eddy, Inc., Boston, MA.
E. L. Stover, R. N. Jarnis, and J. P. Long.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-172272, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-040, May 1981. 8 p, 5 Fig, 1 Tab.

Descriptors: *Municipal wastewater, *Disinfection, *Wastewater treatment, *Ozonation, *Coliforms, Effluents, Water quality standards, Secondary wastewater, Design criteria, Sanitary engineering, Cost analysis, Filtered wastewater.

A 20-month operating experimental program conducted at Marlborough, Massachusetts, evaluated the feasibility, engineering, and economic aspects of achieving high-level effluent disinfection with ozone. The ozone research pilot facility had a maximum flow of 4.4 L/s (70 gpm), and was designed to operate with a constant wastewater flow rate or diurnal flow characteristic. Two effluent qualities (filtered nitrified and filtered secondary) were evaluated to assess water quality impacts on disinfection performance with ozone. The required absorbed ozone concentration to achieve specific levels of disinfection depended on water quality. Absorbed ozone concentrations of 15 to 20 mg/L and 35 to 40 mg/L were required to achieve high-level disinfection of less than 2.2 total coliforms/100 mL and 5 to 8 mg/L and 15 to 20 mg/L to achieve disinfection to 70 total coliforms/100 mL with the Marlborough filtered nitrified and filtered secondary effluent, respectively. Impacts of carrier gas ozone concentration, carrier gas flow rate, gas-to-liquid ratio, and applied ozone dose on contactor transfer efficiencies with both effluent qualities were defined. Water quality, transfer efficiency, and absorbed ozone concentrations are key factors affecting disinfection performance that must be evaluated for efficient design of ozone disinfection systems. Generator and contactor monitoring or mapping procedures and results using both air and oxygen carrier gases are presented as an approach for determining the economical ozone generator operating range and optimal ozone transfer efficiency. JOINT DRY/WET WEATHER TREATMENT OF MUNICIPAL WASTEWATER AT CLATSKANIE, OREGON,

Whiteley-Jacobsen and Associates, Portland, OR.
A. H. Benedict, and V. L. Roelfs.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187262, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-061, June 1981. 4 p, 3 Tab.

Descriptors: *Municipal wastewater, *Wastewater treatment, *Wastewater facilities, High flow, Low flow, Clarification, Activated sludge process, Dissolved air flotation, Effluents, Water quality, Cost analysis, Sewer systems, Capital costs.

The joint dry/wet weather wastewater treatment facility at the small community of Clatskanie, Oregon, underwent a 2-year evaluation. Wet weather flows (WWF), as much as 6 to 10 times dry weather flows, result from severe infiltration/inflow (I/I) to the collection system. Rather than undergo expensive sewer rehabilitation, the treatment facility was designed to process flows ranging from 0.13 to 1.25 mgd (490 to 4730 cu m/day) where average dry weather flow is 0.2 mgd. During dry weather, the plant operates up to 0.5 mgd with primary clarification and an activated sludge mode. For higher flows, the plant can be run in a contact-stabilization mode and the primary clarifier can be operated in a dissolved air flotation (DAF) mode. The waste activated sludge generated during dry weather operation is held as standby sludge for the contact-stabilization operation. Average TSS and BOD concentrations in the effluent of dry weather flows were 10 mg/l and 13 mg/l, respectively, and for WWF the respective concentrations were 2-39 mg/l and 6-20 mg/l. Operating criteria and performance capabilities were developed to assist in other potential applications. The capital cost of the DAF-contact stabilization capability was estimated to be 14% over the cost of a standard dry weather flow plant. The annual operation and maintenance cost was estimated to be 3% over the operation and maintenance cost of a standard dry weather flow plant. The results indicate that for other communities this treatment scheme may be more cost effective than extensive sewer rehabilitation provided the community is in the process of upgrading its treatment plant. For this approach to be a long-term solution to the I/I problem, however, the community must continue a sewer rehabilitation program, or an inflow control program, or both to keep pace with the growth of the city. RECLAIMING AND REUSING WASTEWATER,
California Univ., Berkeley.
W. H. Bruvold, and J. Cook.
Water/Engineering and Management, Vol 128, No 4, p 65, 66, 68, 69, 71, April, 1981. 3 Tab, 11 Ref. OWRT-A-061-CAL(2).

Descriptors: *Reclaimed water, *Public opinion, Attitudes, Public health, Surveys, Wastewater treatment, Water treatment, Drinking water.

A study was performed to assess current public attitudes toward the use of reclaimed water for drinking, employing standard survey research procedures and a quantitative measure of attitudes. An assessment was then made of relations of the attitudes thus quantitated with sociodemographic and belief variables. The general recommendations resulting from the survey favored wastewater treatment and reuse comprising advanced waste treatment followed by beneficial reuse not involving a high degree of human contact. Public support for such proposals can be gathered in general by arguing that the public health is protected, that there is a need to conserve scarce water supplies, and that the environment will be protected from unnecessary degradation. Economic advantages of using reclaimed water could be of interest to the less affluent and more elderly population groups. Through such efforts the reuse of wastewater after treatment will gain support from the public, which is necessary if it is to be implemented. (Baker-FRC)
W82-00402

HIGH PH TREATMENT OF COMBINED WATER SOFTENING AND WASTEWATER SLUDGES,
Iowa Univ., Iowa City.
R. R. Dague, J. N. Veenstra, T. W. McKim, T. G. Ashenmacher, and J. M. Lannon.
Journal of the Water Pollution Control Federation, Vol 52, No 8, p 2204-2219, August, 1980. 24 Fig, 4 Tab, 32 Ref. OWRT-A-062-IA(1).

Descriptors: *Lime, *Bacteria, *Hydrogen ion concentration, *Disinfection, Sludge treatment, *Wastewater treatment, Coliforms, Water treatment, Activated sludge, *Water softening.

Water softening sludge combined with waste water sludge was studied in a 2-phase investigation of the effects of high pH on bacterial survival. From 99.44 to 99.98% of fecal coliforms in waste water sludge alone were killed at pH values between 11.0 and 12.2 at 20C and 35C after 1 hour. Total aerobes were slightly hardier--under the same conditions 98.58-99.87% were killed. Fecal streptococci were even more resistant: 93-96% died after 1 hour at pH 12.2, temperature 20C and 35C, and more survived at lower pH. Grow-back occurred at 20C and 35C, especially in fecal coliforms. After 48 hours, these bacterial counts exceeded baseline counts at all pH tested (5.8-12.2) except for pH 11.8 and 12.2 at 20C. Total aerobes showed slight grow-back at pH 11.8 from the 1 hour kill levels, increasing as pH decreased from that point. Fecal coliforms had the least tendency to grow back, showing larger than baseline counts only at pH 5.8. Adding chemical water softening sludges to primary waste water sludge somewhat reduced the amount of hydrated lime required to reach and maintain a pH of 12.0 for 15 days. The chemical quality of the combined sludge improved vacuum filter dewatering performance in terms of total cake solids and filter yields. However, when applied to mixtures of waste activated sludge and primary waste water sludge, high pH treatment increased COD, BOD, and total Kjeldahl nitrogen in filtrates from dewatering operations and produced no reduction in lime requirements. (Cassar-FRC)

DESIGN, EVALUATION AND EFFLUENT WATER QUALITY ANALYSIS OF THREE OYSTER SHELLSTOCK WASHERS,
Mitre Corp., McLean, VA.
S. S. Chang, and F. W. Wheaton.
Transactions of the ASAE, Vol 24, No 1, p 234-241, January-February, 1981. 4 Fig, 4 Tab, 17 Ref. OWRT-A-033-MD(2).

Descriptors: *Oysters, *Waste water treatment, *Food-processing wastes, Water quality control, Biochemical oxygen demand, Chemical oxygen demand, Waste water analysis, Hydrogen ion concentration, Water quality standards, Maryland, Industrial waste water, Disinfection.

Due to pressure from the Food and Drug Administration and state health officials, the washing of oyster shellstock in Maryland is becoming a more common practice in the oyster industries. Three techniques of washing oyster shellstock were evaluated for their effectiveness of cleansing oysters. The two methods giving the best cleaning results were examined for wash water quality to determine the need for waste water treatment in oyster processing plants. A rotary tumbler, a rotary brush washer, and a pressurized water spray washer were designed and constructed. Methods which gave the best results were examined for fifteen water quality parameters. Results of the water quality analysis showed that the effluent must be disinfected prior to discharge. It was also found that in some cases, the effluent pH should be lowered to comply with existing EPA standards and regulations set down by the state of Maryland. The practice of washing oyster shellstock will add biochemical oxygen demand, chemical oxygen demand, bacteria, suspended solids, filterable solids and settleable solids to the waste water of oyster processing plants. CONTINUOUS BIOREGENERATION OF GRANULAR ACTIVATED CARBON DURING THE ANAEROBIC DEGRADATION OF CATECHOL,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
M. T. Suidan, W. H. Cross, and M. Fong.
Progress in Water Technology, Vol 12, No 6, p Tor 203-214, 1980. 5 Fig, 4 Tab, 13 Ref. OWRT-A-077-GA(2).

Descriptors: *Activated carbon, *Tertiary treatment, *Filters, *Waste water treatment, Organic wastes, Industrial wastes, Adsorption, Separation techniques, Methane, Chemical oxygen demand, Biodegradation, Biological treatment, Aromatic compounds, Anaerobic conditions.

An anaerobic activated carbon filter consisting of four jacket columns and three clarifiers was used to treat a synthetic waste water containing catechols. Catechol was removed from the feed solution mainly by adsorption onto the activated carbon during the initial acclimatization period. Following acclimatization, vigorous anaerobic activity took place, which generated a greater total carbon equivalent in the gaseous products than was removed as organic carbon during anaerobic bioregeneration of the activated carbon. When the period of vigorous anaerobic activity was finished, the production of gas returned to a level corresponding to the amount of organic carbon removed during the treatment process. Steady-state operating conditions were found at all three feed concentrations of catechol tested, which corresponded to 200, 400, and 1,000 milligrams/liter. With the present device, total organic carbon reductions exceeded 81%, while chemical oxygen demand removals of 95% were achieved. (Geiger-FRC)

PROCESSING NEEDS AND METHODOLOGY FOR WASTEWATERS FROM THE CONVERSION OF COAL, OIL SHALE AND BIOMASS TO SYNFUELS.
California Univ., Berkeley. Dept. of Chemical Engineering.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0081, Price codes: A09 in paper copy, A01 in microfiche. Department of Energy Report DOE/EV-0081, May 1980. 185 p, 1 Fig, 3 Tab, 17 Ref, 15 Append. DE-AT03-79EV10227.

Descriptors: *Process water, *Wastewater treatment, *Oil shale, *Coal gasification, *Biomass, Fuel, Industrial wastes, Water use, Water reuse, Pollution load, Pollutants, Effluents, Water pollution control, Sludge disposal, Water conservation.

This report stems from the workshop held at Germantown, Maryland, 14-15 June 1979, with the purpose of identifying needs to be accomplished by processing technology and evaluating the suitability, approximate costs and problems associated with wastewaters from the conversion of coal, oil shale and biomass to synfuels. Water usage may be very high, but can be reduced by recycling within the plant. Some possible effluent levels from pollutants are suggested. Costs are presented for gravity separation techniques, steam stripping, solvent extraction, bio-treatment, carbon adsorption, iron precipitation, ozonation, wet-air oxidation, ion exchange, incineration, deep-well injection, and concentration processes, with their technical advantages and disadvantages. The critical environmental control issues are identified as total dissolved solids, polynuclear aromatic hydrocarbons and nitrogen heterocyclics, ammonia or nitrate, color, arsenic and other heavy metals, boron, toxicity safeguard, disposal of sludges, carbon regeneration effluent, and secondary effluent. Water handling and treatment should be considered as an integral part of a specific fuel conversion process, and the possibilities of recycling and reuse explored to reduce water demand. Each appendix is an individual status report on wastewater processing and methodology. (See W82-00432 thru W82-00445) (Brambley-SRC)

ASSESSMENT OF ENVIRONMENTAL CONTROL TECHNOLOGY FOR COAL CONVERSION PROCESSES,
Oak Ridge National Lab., TN.
J. A. Klein.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p B1-B6, 1 Fig, 3 Ref.

Descriptors: *Coal, *Wastewater treatment, *Coal gasification, *Biodegradation, *Adsorption, *Ozonation, Bacteria, Organic compounds, Phenols, Hydrocarbons, Industrial wastes.

The effectiveness of various treatment systems for the cleanup of aqueous coal conversion wastes is being investigated. A flow sheet of a number of waste treatment units was developed, and three have been investigated as independent units. A tapered fluidized-bed bioreactor containing bacteria on a support of coal or sand has been used with and without oxygen. The bioreactor can reduce phenol to < or = 1 microgram/cu cm, thiocyanate to 1-5 microgram/cu cm and total soluble organics by 95%. Adsorption experiments have attempted to find a substitute for activated charcoal, and a Texas lignitic coal was found to reduce 90% of the polynuclear aromatic hydrocarbons (PAH) and 9% of the total organic carbon content of a hydrocarbonization water. Ozonation has been investigated as a final cleanup step, to remove those compounds which pass through biological treatment. Ozonation can reduce PAH and phenol levels by 95-98%, with contact times of 15 min or less. The most effective integration of these units with others has yet to be achieved. (See also W82-00431) (Brambley-SRC)
W82-00432

SLAGGING FIXED-BED GASIFIER (SFBG) WASTEWATER PRETREATMENT,
Department of Energy, Grand Forks, ND. Grand Forks Energy Technology Center.
W. G. Willson.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p C1-C4.

Descriptors: *Coal gasification, *Wastewater treatment, *Industrial wastewater, *Waste characteristics, Effluents, Zero discharge, Waste disposal, Economic aspects, Environmental effects.

The Grand Forks Energy Technology Center's 24-ton/day slagging fixed-bed gasifier (SFBG) is the only operable unit of its type in the United States, and affords many research opportunities in the coal gasification process. Commercially available waste water treatment processes appear to be applicable to coal gasification waste streams, but each treatment plant will need appropriately designed units to meet the specific technology and feedstock requirements and the environmental and economic constraints at each particular installation. The SFBG can be used with low-rank and bituminous coals to develop such specific information, and by sampling and analysis of waste streams to characterize gaseous, solid, and liquid effluents, and by testing of treatment processes, may establish the feasibility of zero discharge of liquids and safe disposal of solid wastes. The economics of the treatment processes must also be determined. (See also W82-00431) (Brambley-SRC)
W82-00433

TREATMENT OF COAL GASIFICATION PROCESS WASTEWATERS,
Carnegie - Mellon Univ., Pittsburgh, PA. Dept. of Civil Engineering.
R. C. Luthy.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p D1-D9, 2 Fig, 11 Ref.

Descriptors: *Coal gasification, *Process water, *Wastewater treatment, *Biological wastewater treatment, Effluents, Nitrification, Adsorption, Reverse osmosis, Ion exchange, Cyanide, Ammonia, Phenols, Economic aspects, Hydrocarbons, Chemical oxygen demand.

Biological treatment, alone or with physicochemical treatment is an important method of upgrading coal gasification wastewaters. Studies have been conducted using two different wastewaters and different dilutions to determine removal efficiencies and cell residence times. Nitrification was feasible with the slagging fixed-bed pilot plant effluent, but not with the Hygas pilot plant effluent. Nitrification efficiency with stripped wastewater was greatest at low COD removal rates. Up to 100 mg/l cyanide could be treated without difficulty. Both wastewaters required dilution or ammonia stripping to overcome ammonia toxicity. Phenol recovery by solvent extraction is believed to be technically feasible but economically uncertain. Ultimately the need to protect the biological reactor from shock organic loads and to remove refractory organic compounds may outweigh economic considerations. Ion exchange studies have shown good breakthrough characteristics and capacities for biological reactor effluent which had been pretreated by activated carbon adsorption for residual organic removal. Reverse osmosis was not as effective, and the membrane characteristics deteriorated rapidly. Powdered activated carbon tratment provided greater removal of COD and polynuclear aromatic hydrocarbons. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p E1-E7, 3 Ref.

Descriptors: *Coal gasification, *Water pollution sources, *Wastewater treatment, *Process water, Biological wastewater treatment, Filtration, Phenols, Ammonia, Suspended solids, Fluorides, Organic compounds, Runoff, Leachates.

The environmental factors and control technologies involved in the flash hydropyrolysis of coal for the production of gaseous and liquid hydrocarbon fuels and feedstocks are assessed. An aqueous phase is produced in the process which contains ammonia, phenols, cyanide and thiocyanate in proportions depending upon the original coal and the hydropyrolysis conditions. Facilities to treat these liquid wastes include a degasifier and condensate cooler, phenol remover, biological treatment reactor, and final wastewater treatment unit. Filtration to remove suspended solids and lime treatment to remove fluoride ions may also be required. Phenols can be removed by solvent extraction using isopropyl ether or oil. Biological treatment can be used to remove nitrogen, phosphorus and sulfur compounds and some organics, but not aromatic hydrocarbons or trace metals. Additional water pollution problems may arise from run-off from the coal before processing, and the leachate from disposal of the coal refuse. (See also W82-00431) (Brambley-SRC)
W82-00435

CHEMICAL RECOVERY FROM COAL CONVERSION WASTES BY CONCENTRATION,
Concentration Specialists, Inc., Andover, MA.
W. R. Killilea.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p F1-F6, 2 Fig.

Descriptors: *Coal gasification, *Wastewater treatment, *Wastewater renovation, *Water reuse, *Chemical recovery, Phenol, Ammonia, Freeze crystallization, Incineration, Cost analysis, Cooling water, Waste disposal.

A study was conducted to determine the feasibility of using concentration processes to recover chemical by-products from the gas liquor stream of a coal gasification plant and to produce reusable water. Large quantities of gas liquor are produced containing high concentrations of phenol and ammonia. Reverse osmosis and evaporation were investigated and rejected whereas freeze crystallization was practical and economically cost-effective. A three-stage freezing system was designed, in which pure water freezes first and is removed; continued cooling results in the precipitation of ammonium carbonate, and then of phenol. Each solid product is washed to remove surface contamination and the wash water returned to the gas liquor feed. The water obtained from the melted ice can be used as cooling tower water with some make-up water, and the remaining heavily contaminated water can be disposed of by chemical fixation, incineration, or return to the gasifier. Based on current, available costs, with the three-stage freezing process and incineration of the waste concentrate, a return of 80 cents/1000 gallons can be achieved. IMPROVED WATER MANAGEMENT OF COAL CONVERSION PROCESSES BY PRELIMINARY ABSORPTION OF HALIDES,
McKee (Arthur G.) and Co., Cleveland, OH.
W. A. Parsons.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p G1-G5.

Descriptors: *Coal gasification, *Wastewater treatment, *Halogens, *Condensates, Dissolved solids, Cost analysis, Incineration, Evaporation, Waste disposal, Desalination, Desalination wastes, Reverse osmosis.

The technical, economic and environmental advantages and disadvantages of single stage and two stage gas quenching at a producer gas installation were compared. Air-blown and oxygen-blown gasifier operations were used with a high halide Illinois coal and a low halide Montana coal. A first stage quench condensing 10 gallons of water/ton of coal by either a sieve tray absorber or a venturi scrubber was determined to be effective for absorption of halides. The secondary condensate was amenable to recovery as a low dissolved solids service water after processing by steam stripping and activated sludge treatment. The two stage quench system was cost effective with the Illinois coal whereas the single quench system was cost effective for the Montana coal. The dominant variable in determining the cost effectiveness was the halide content. For halide concentrations, expressed as chloride, above 0.15% and 0.16%, for air-blown and oxygen-blown gasifier operations, respectively, the two stage system is cost effective, while for lower halide concentrations the single quench system is cost effective. The preferred disposal concept for inorganic wastewater blown down from a high halide coal operation was incineration with disposal of salt cake at sea, using a two stage quench system in conjunction with desalination by reverse osmosis and thermal evapora-

tion. When low halide coal is used the preferred disposal concept was pond evaporation, using a single quench system in conjunction with desalination by reverse osmosis. (See also W82-00431) (Brambley-SRC)

SOLVENT EXTRACTION OF PHENOLS,
California Univ., Berkeley.
C. J. King, S. Lynn, D. N. Hanson, D. C. Greminger, and G. P. Burns.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewater from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p H1-H8, 3 Fig, 1 Tab, 2 Ref.

Descriptors: *Coal gasification, *Wastewater treatment, *Phenols, *Organic solvents, Solubility coefficient, Waste recovery, Molecular structure, Temperature, Hydrogen ion concentration, Diisopropyl ether, Methyl isobutyl kentone.

The Lurgi Phenosolvan process for solvent extraction from coke-oven waters using diisopropyl ether as the solvent has been suggested as a method of phenol removal from coal-conversion plant wastewaters. This may not be possible because of the significant quantities of polyhydric phenols in the coal-conversion wastewaters, and the high pH of the wastewater, and because of the need to simplify the Phenosolvan process and to determine the most appropriate temperature for the process. The presence of a carbonyl group increases hydrogen bonding with the hydroxy groups of the phenols, so based on its miscibility, volatility and stability properties methyl isobutyl ketone (MIBK) was selected as a test solvent. The distribution coefficients for 6 polyhydric phenols into MIBK were determined. The values obtained showed that MIBK extraction could be practical. The distribution coefficient for phenol into MIBK decreased with increasing temperature, suggesting that the extraction process could be carried out at low temperatures, which could favor vacuum stripping. For both phenol and resorcinol the distribution coefficient in diisopropyl ether decreases with increasing pH, and is significantly reduced in the pH range of coal-conversion wastewaters, whereas the distribution coefficient for phenols into MIBK is significantly higher at low pH. ASSESSMENT OF SOLVENT EXTRACTION FOR TREATMENT OF COAL GASIFIER WASTEWATER,
Missouri Univ.-Columbia.
R. H. Luecke.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p I1-I8, 3 Tab, 8 Ref.

Descriptors: *Coal gasification, *Wastewater treatment, *Phenols, *Organic solvents, Pollutants, Capital costs, Operating costs, Cost analysis, Waste recovery, Octanone, Economies of scale.

Solvent extraction of organic pollutants from coal gasification plant waste streams may overcome some of the problems associated with other methods. To make the process efficient a dual extraction process is recommended, in which the wastewater is contacted counter-currently with a polar solvent and then in another contactor with a non-polar solvent. The solvent streams are processed in separate distillation systems, with the pollutants being recovered and the solvents recycled to appropriate extraction. A design for an extraction system using 2-octanone has five stages, which will remove hydroquinone at 75% efficiency, catechol at 95%, resorcinol at 99%, and phenol, cresols and xylenols at 99.99% efficiencies. The process is relatively complex and hence expensive. The capital investment for a plant to treat 100 gpm of wastewater is about $0.5 million, and for a 1000 gpm plant is $1.7 million. Operating costs range up to $6.50/1000 gallons, compared to about $0.40/1000 gallons for biological treatment, indicating that a sizeable return on the recovered pollutants is necessary to justify the solvent extraction wastewater treatment process. CONTROL TECHNOLOGY STRATEGIES FOR COAL PREPARATION WASTE DRAINAGES,
Los Alamos Scientific Lab., NM.
P. Wagner, J. M. Williams, J. P. Bertino, L. E. Wangen, and P. L. Wanek.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p J1-J8, 5 Tab.

Descriptors: *Wastewater treatment, *Mine wastes, *Water pollution control, *Acid streams, Coal mining, Calcining, Wastedisposal, Bases, Chemical reactions, Leachates, Dissolved solids, Hydrogen ion concentration, Trace elements, Cost analysis.

Laboratory investigations were conducted into the options available for treating high-sulfur coal refuse materials by calcining to immobilize refuse constituents, codisposal of wastes with alkaline materials, and by treating the contaminated drainage from refuse dumps. A high-sulfur coal preparation waste was calcined at temperatures up to 1200C for 2h. Mineral conversion reactions took place which resulted in reductions of up to two orders of magnitude of toxic elements in the leachate. Addition of 3 and 10% by weight of lime to the same coal waste with subsequent drying and recrushing effectively reduced the acidity of leachates, and lowered the total dissolved solids and the trace element concentrations. Smaller lime additions were not effective. Contaminated refuse drainages from three plants were titrated with limestone, lime or sodium hydroxide to a predetermined pH. Raising the pH was associated with a reduction of total dissolved solids. All the methods are effective in reducing or abating trace element contamination of coal refuse drainage, but they differ significantly in cost, process complexity, treatment duration, by-products potential, permanency, and categorization of the waste for Resource Conservation and Recovery Act purposes. CHARACTERIZATION AND PROCESSING OF COAL CONVERSION PROCESS WASTEWATERS,
Department of Energy, Pittsburgh, PA. Pittsburgh Energy Technology Center.
G. E. Johnson, and C. J. Drummond.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p K1-K14, 8 Fig, 2 Tab.

Descriptors: *Coal gasification, *Wastewater treatment, *Process water, Water pollution control, Phenols, Ammonia, Hydrocarbons, Oil, Activated carbon, Adsorption, Nitrification, Chemical precipitation, Biochemical oxygen demand, Oxidation.

A commercial coal gasification plant is expected to produce about 3 mgd of process waters containing phenols, ammonia, polynuclear aromatic hydrocarbons, and other pollutants, which must be treated. The Synthane process produces a byproduct char which has been partially activated, and has the properties of a low grade activated carbon. It can be used as an adsorbent for Synthane process condensates, either as a primary treatment step or as a tertiary polishing step following biochemical oxidation. The other units of the treatment system are nitrification, and oil and tar precipitation. Ammonia is removed to about 500 mg/l by batch stripping with nitrogen at 90C. Oils and tars are precipitated by acidification to pH 2.5 with phosphoric acid, followed by lime neutralization. A complete mix, continuous unit with sludge recycle has been produced for biochemical oxidation. The separate units have been integrated to produce a treatment sequence with a flow capacity of 6 gal/h. (See also W82-00431) (Brambley-SRC)

BIOLOGICAL OXIDATION OF AQUEOUS THIOCYANATE,
Pittsburgh Univ., PA. Dept. of Civil Engineering.
R. D. Neufeld, L. Mattson, and P. Lubon.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p L1-L10, 7 Fig, 2 Tab, 12 Ref.

Descriptors: *Coal gasification, *Wastewater treatment, *Thiocyanates, *Biological oxidation, Effluents, Pollution load, Kinetics, Sludge volume index, Pilot plants, Steel industry, Industrial wastes.

Depending on the coal and the gasification conditions, coal gasification produces effluents containing 35-1250 mg/l of thiocyanate. Research has been conducted to develop a kinetic expression and material balance for nitrogen and sulfur for the biological oxidation of aqueous thiocyanates as found in coal conversion and steel industry wastewaters. Biochemical degradation of thiocyanate yields sulfate, sulfide, and ammonium ions. Experiments were conducted in fill and draw semicontinuous reactors with 3.5 or 8 1 working volumes, sludge age of 5-15 days, pH of 7 or 8, and an organism which used thiocyanate as the sole carbon source. Specific utilization of thiocyanate increases with substrate concentration up to about 550 mg/l, when it becomes inhibitory. A representative yield coefficient for thiocyanate degrading organisms was about 0.127 lb volatile suspended solids/lb thiocyanate. The biooxidation process seems to be unstable at sludge ages of less than four days. In this system 89-106% of the thiocyanate nitrogen was accounted for as ammonia, and 90-97% of the thiocyanate sulfur was accounted for as sulfate. Sludge settling rates and volume are considered good, and should pose no problems in clarification processes. (See also W82-00431) (Brambly-SRC)

WATER-RELATED ENVIRONMENTAL CONTROL REQUIREMENTS OF WASTE-TO-ENERGY CONVERSION,
Iowa State Univ., Ames.
J. C. Young.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche.
In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p M1-M5, 2 Tab.

Descriptors: *Wastewater treatment, *Water pollution control, *Water pollution prevention, *Fuel, Wastewater analysis, Water quality standards, Pollutants, Solid waste disposal, Biomass, Anaerobic digestion, Biological wastewater treatment, Leachates.

Laboratory-scale tests have been conducted with wastewaters from four waste-to-energy conversion processes to determine their treatability by conventional and advanced technology, their impact on biological treatment systems, and the leaching characteristics of their solid residues and sludges. Problems common to all the processes are the lack

LIBRARY U. OF I. URBANA-CHAMPAIGN

of dependable test methods for analyzing wastewaters for priority pollutants and other constituents, the lack of definite discharge standards for priority pollutants, and uncertainty over methods of solid residue disposal. Specific water related pollution technologies have been identified for each waste-to-energy conversion process. Physical and/or chemical treatment is suitable for controlling the inorganic compounds resulting from mass-burning. Dry processing of refuse derived fuel produces wastes which can be discharged to municipal sewers, if the ash sluice waters are recycled. The wastes from wet processing facilities can be treated by biological and chemical methods. Pyrolysis processes produce priority pollutants which may be treated by biological or chemical methods, but may not achieve reduction to permissible discharge levels. Priority pollutants from anaerobic digestion processes tend to be adsorbed to the residual solids, posing the problem of leachate from the ultimate disposal site. Biological or chemical methods can be used to treat the wastewater. (See also W82-00431) (Brambley-SRC)

ENVIRONMENTAL CONTROL TECHNOLOGY FOR SHALE OIL WASTEWATERS,
Battelle Pacific Northwest Lab. Richland, WA.
B. W. Mercer.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p N1-N14, 3 Fig, 5 Tab.

Descriptors: *Oil shale, *Wastewater treatment, *Water pollution control, *Pollution load, Ammonia, Organic compounds, Biochemical oxygen demand, Chemical oxygen demand, Suspended solids, Heavy metals, Cost analysis, Water reuse.

Studies have been conducted to assess current technology for the treatment and disposal of shale oil wastewaters to maintain acceptable quality levels in the receiving waters of the oil shale regions presently under development. The wastewaters are highly contaminated with ammonia, BOD, refractory organics, and salinity, a stable suspension of organic matter, and with toxicants such as arsenic which may interfere with biological treatment. Treatment by a series of units is necessary to obtain satisfactory reduction of pollutants. Raw retort water treated by suspended matter removal, ammonia removal, BOD removal, suspended solids removal, dissolved organics removal, and dissolved salts removal is of a quality suitable for discharge or reuse. Ammonia was removed by steam stripping; activated sludge and activated carbon were used to remove BOD and COD, respectively. Costs for the treatment range from $26-45.00/1000 gal. The water can be reused for steam generation or cooling purposes. (See also W82-00431) (Brambley-SRC)
W82-00444

POTENTIAL USES OF SPENT SHALE IN THE TREATMENT OF OIL SHALE RETORT WATERS,
California Univ., Berkeley. Lawrence Berkeley Lab.
J. P. Fox, and D. L. Jackson.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0081, Price codes: A09 in paper copy, A01 in microfiche. In: Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels, Department of Energy Report DOE/EV-0081, May 1980. p 01-020, 5 Fig, 6 Tab, 8 Ref.

Descriptors: *Oil shale, *Wastewater treatment, *Organic carbon, *Adsorption, Specific conductivity, Hydrogen ion concentration, Inorganic carbon, Odor control, Color removal, Water pollution control.

Spent shale has two potential applications in wastewater purification - circulation of water through a spent in situ retort, and circulation of water through columns packed with spent shale from surface retorts. Batch and column studies were conducted with four samples of retort water and six of spent shale to determine the effects on dissolved organic carbon (DOC), dissolved inorganic carbon (DIC), conductivity and pH. In the batch studies reductions in DOC of up to 73% were achieved and up to 99% of DIC. Spent shales with the highest DOC adsorptive capacity are least effective in DIC removal and vice versa. The reduction in DIC levels is accompanied by a decrease in conductivity and an elevation in pH. In the column experiments the color and odor of retort water was almost completely removed by the spent shale, and some organic compounds were removed, but column breakthrough occurred before two pore volumes could be treated. If this problem is overcome, passage through spent shale could become a useful treatment process. It makes ammonia stripping easier by increasing the pH, and by reducing DIC, DOC and conductivity, it decreases the load on these treatment units. (See also W82-00431) (Brambley-SRC)

THE HARVEST OF MICROALGAE FROM THE EFFLUENT OF A SEWAGE FED HIGH RATE STABILIZATION POND BY TILAPIA NILOTICA. PART 1: DESCRIPTION OF THE SYSTEM AND THE STUDY OF THE HIGH RATE POND,
Asian Inst. of Tech., Bangkok (Thailand). Div. of Agricultural and Food Engineering.
P. Edwards, and O-A. Sinchumpasak.
Aquaculture, Vol 23, No 1-4, p 83-105, April, 1981. 4 Fig, 3 Tab, 27 Ref.

Descriptors: *Stabilization ponds, *Wastewater treatment, *Phytoplankton, Algae, Experimental design, Design criteria, High flow, Growth.

A sewage-driven, two trophic level food chain involving phytoplankton produced in a high rate stabilization pond and herbivorous Tilapia nilotica raised in associated fish ponds was studied to determine factors affecting fish growth and to assess the fertilization potential of the fish pond effluent for maize cultivation. The waste treatment and recycling system consisted of a 200-square-meter high rate stabilization pond, a series of 4-cubic-meter concrete fish ponds, and a maize plot. The sewage fed to the stabilization pond was weak, with a mean 5-day biological oxygen demand of 45 mg per liter and a mean surface organic loading of 75 kg of 5 day biological oxygen demand per hectare per day. As a result, the pond was nutrient limited, not light-limited. The mean phytoplankton concentration was 94 milligrams per liter, with a detention time of 3 days, and the mean phytoplankton yield was 15.7 grams per square meter per day. It should be possible to achieve at least double this yield in a high rate stabilization pond in Thailand without nutrient limitation. The wide variety of dominant phytoplankton recorded in the high rate stabilization pond may have been due either to the weak sewage or to the lack of seasonal temperature changes. Although the phytoplankton community was generally stable, it collapsed on two occasions. There were no discernible seasonal variations in the composition of the phytoplankton community. MANAGEMENT AND DESIGN IMPLICATIONS OF A MATHEMATICAL MODEL OF A RAPID GRAVITY SAND FILTER BACKWASH,
Rodbourne Water Pollution Control Plant, Swindon (England).
J. Hilton, and K. V. Whitehall.
Water Research, Vol 15, No 8, p 1013-1017, August, 1981. 3 Fig, 2 Ref.

Descriptors: *Mathematical models, *Backwash, *Gravity filters, Sand filters, Filtration, *Wastewater treatment, Water treatment, Design criteria.

A model of the hydraulic system of backwashing was developed and tested. The model assumes that above the media surface the direction of flow is horizontal towards the weir, that below the media surface flow is vertical, and that the two are instantaneous. The model is applied to the problem of sand loss in rapid gravity filters. This theory suggests a new remedy involving the reduction of the bed length. Also, it suggests the use of closely spaced longitudinal weirs. The model is also applied to investigate backwash times. An equation is presented to determine the minimum length of backwash required to obtain an acceptably clean bed. The model can determine the length of backwash necessary in order to obtain maximum removal of solids with minimum use of backwash water. (Small-FRC)

LOW TEMPERATURE REMOVAL OF NITRATE BY BACTERIAL DENITRIFICATION,
Trondheim Univ. (Norway).
G. Halmo, and K. Eimhjellen.
Water Research, Vol 15, No 8, p 989-998, August, 1981. 4 Fig, 7 Tab, 14 Ref.

Descriptors: *Denitrification, *Activated sludge process, *Bacteria, *Wastewater treatment, Biological treatment, Nitrates, Nitrification, Domestic wastes, Temperature effects.

Enrichments of psychrophilic denitrifying bacteria were tested to further understand the problems associated with low-temperature denitrification in wastewater treatment. Two denitrifying sludges enriched at 5 and 20 deg C were exposed to the same chemical and hydraulic conditions, and sludge efficiency was determined. In the range 0-17 deg C, the specific denitrification rate of the low temperature sludge was 1.5-4 times the high temperature sludge rate. Also, at 2 deg C under nitrate limiting conditions, 98% nitrate reduction was found at a hydraulic resistance time of 3.5 hr with an influent concentration of 0.8 mg N03-N per liter. Low temperature sludge also had better sedimentation characteristics. The low temperature sludge consisted predominantly of psychrotrophs/psychrophiles and had low concentrations of mesophiles. Low temperature sludges tested in a three stage biological process receiving domestic sewage gave 90% removal of total nitrogen at hydraulic residence times of 1.5, 9, and 4 hr for two aeration stages and an anaerobic stage, respectively. Overall nitrification/denitrification was 95%. (Small-FRC)

TESTING THE FLOCCULATION/COAGULATION OF WASTEWATER BY GRANULOMETRIC ANALYSIS OF SUSPENDED SOLIDS IN THE WATER USING A LASER DIFFRACTION METER,
Centre de Recherche de l'Omnium d'Assainissement, Colombes (France).
C. Casellas-Salha, F. Acobas, J. Bontoux, and H. Moreaud.
Water Research, Vol 15, No 8, p 969-975, August, 1981. 12 Fig, 1 Tab, 20 Ref.

Descriptors: *Flocculation, *Suspended solids, Measuring instruments, *Lasers, *Wastewater treatment, Performance evaluation, Coagulation.

The optimization and control of the flocculation/coagulation process were investigated, and a parameter which expresses the efficiency of flocculation was defined and measured. A granulometric analysis of the suspended solids in the flocculated supernatant revealed that the concentration of particles between 1.5 and 10 micrograms could be a satisfactory control parameter. A laser diffraction meter is capable of making this measurement and has the necessary sensitiveness, reliability, short response time, and ease of automation. The instrument was calibrated by measuring suspended solids remaining in supernatants using water of various qualities. The unit can be used for continuously controlling the quality of the effluent from a physical/chemical wastewater treatment plant. Also, it could be used to determine the quality of raw water for a water treatment facility. (Small-FRC)

RESPONSE OF BACTERIA IN WASTEWATER SLUDGE TO MOISTURE LOSS BY EVAPORATION AND EFFECT OF MOISTURE CONTENT ON BACTERIAL INACTIVATION BY IONIZING RADIATION,
Sandia National Lab., Albuquerque, NM.
R. L. Ward, J. G. Yeager, and C. S. Ashley.
Applied and Environmental Microbiology, Vol 41, No 5, p 1123-1127, May, 1981. 2 Fig, 2 Tab, 15 Ref.

Descriptors: *Sludge, *Moisture content, *Enteric bacteria, *Wastewater treatment, *Bacteria, Sewage bacteria, Liquid sludge, Survival, Population density, Population dynamics, Sludge drying, Ionization, Gamma radiation, Irradiation.

The potential use of sand-bed drying for inactivation of sludge pathogens and subsequent use of ionizing radiation to further disinfect dried sludges raises questions concerning the separate and combined effects of the drying process and ionizing radiation on the survival of enteric bacteria. The survival of six fecally-associated bacteria grown separately in sterilized sludge and of bacteria indigenous to sludge was examined following sludge dewatering and dewatering with subsequent treatment by ionizing radiation. Initial phases of sludge dewatering resulted in stimulation of bacteria growth, but reductions in moisture content below about 50% by weight caused a proportional reduction in bacterial numbers, generally reaching one order of magnitude or less in comparison with the original sludge. The rate of inactivation of bacteria by ionizing radiation in sludge was usually modified to some degree by variations in moisture content. Reduced moisture levels provided some degree of protection from ionizing radiation for most bacteria. The radiation resistance of Salmonella typhimurium was about doubled in dried sludge. However, none of the bacterial species tested required an excessive amount of irradiation to inactivate 90% of their populations. The study results indicate that loss of water by evaporation is not an adequate method for reducing the bacterial population in sludge when used alone. Also, although the rates of bacterial inactivation by ionizing radiation in sludge can be altered by changes in moisture content, the amount and direction of alteration varies with bacterial species. Treatment with ionizing radiation appears to be a feasible method of destroying bacterial pathogens in both liquid and dewatered sludges. (Carroll-FRC)

SURVIVAL OF ENTEROVIRUSES IN RAPID-INFILTRATION BASINS DURING THE LAND APPLICATION OF WASTEWATER,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
C. J. Hurst, C. P. Gerba, J. C. Lance, and R. C. Rice.
Applied and Environmental Microbiology, Vol 40, No 2, p 192-200, August, 1980. 3 Fig, 7 Tab, 25 Ref.

Descriptors: *Enteroviruses, *Land disposal, Wastewater treatment, Infiltration, Infiltration rate, Poliovirus, Flooding, Wastewater disposal, Waste disposal, Effluents, Groundwater pollution.

The measurement of enterovirus downward migration through soil during rapid infiltration of sewage effluent was undertaken. Measurement was also made of enterovirus inactivation rates in soil of rapid-infiltration basins during periods of flooding and drying. The basins used in the study were part of a pilot system designed to study the high-rate land treatment of wastewater for water quality improvement and groundwater recharge. Two field studies were performed. After 5 days of flooding, the amount of seeded poliovirus type 1 that had migrated 5 to 10 cm downward through the soil profile was 11% of that remaining at the initial burial depth. The amount of echovirus type 1 determined to have moved an equal distance was at least 100-fold less. Migration of naturally occurring enteroviruses during infiltration of sewage effluent through soil could not be measured with accuracy because of the possibility of virus survival from previous applications of effluent. The rate of inactivation for seeded poliovirus 1 and echovirus 1 buried in the infiltration basins ranged between 0.04 and 0.15 log-10 units per day during the time the basins were flooded. Inactivation of these same seeded virus types and of indigenous enterovirus populations in the infiltration basins during the drying portion of the sewage application cycle ranged between 0.11 and 0.52 log-10 units per day. The rate of virus inactivation was dependent on the rate of soil moisture loss. These results indicate that drying cycles during the land application of wastewater enhance virus inactivation in the soil. (Baker-FRC)

Available from the National Technical Information Service, Springfield, VA 22161 as PB81-190928, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-064, May 1981. 3 p.

Descriptors: *Electroplating, *Industrial wastewater, *Sludge, *Leaching, Hydrogen ion concentration, Heavy metals, Water pollution sources, *Land disposal, Runoff, Interstitial water.

The problem of disposal and handling of solid wastes from electroplating wastewater treatment systems has been difficult and complex. This three-phase project was initiated to provide information concerning the physical and chemical characteristics of electroplating wastewater treatment sludges and their performance in a leaching environment. Phase I physically and chemically characterized representative electroplating sludges, determined their response to the EPA extraction procedure (EP), and determined the sensitivity of the parameters in the EP. Phase II involved laboratory testing to determine the performance of electroplating sludges under less aggressive leaching conditions than those in the EP. Phase III experiments were designed to validate conclusions drawn from Phase II by conducting field tests on an actual segregated metal hydroxide landfill. Two variables were found to have a major effect on the results obtained by the leaching procedures tested during Phase I: the composition and amount of free and interstitial wastewater present in the sludge, and the pH of the final extract. Electroplating wastewater treatment sludges in general do not leach heavy metals at a significant rate when deionized water is used as a leaching medium. Mildly acidified leaching water results in higher rates of heavy metal leaching. A sample of combined leachate and runoff from a segregated hydroxide landfill was found by analysis to pass drinking water standards. (Moore-SRC)

CROPPING SYSTEMS FOR TREATMENT AND UTILIZATION OF MUNICIPAL WASTEWATER AND SLUDGE,
Michigan State Univ., East Lansing. Dept. of Crop and Soil Sciences.
B. G. Ellis, A. E. Erickson, and L. E. Leach.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187254, Price codes: A10 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-065, July 1981. 9 p, 1 Fig, 5 Tab.

Descriptors: *Wastewater disposal, *Land disposal, *Sludge disposal, *Crop yield, Corn, Forages, Nitrogen removal, Heavy metals, Groundwater contamination, Cost analysis, Municipal wastes.

An attempt was made to develop a cropping system which would remove nitrogen from added wastewater for a longer period than the four weeks in which corn removes nitrogen. Corn was interplanted with red clover, alfalfa, birdsfoot trefoil, and ryegrass which gave satisfactory corn yields. Yields were drastically reduced when corn was grown with tall fescue or orchard grass, and were unchanged when the forage was rye, quackgrass or reed canary grass. All the interplantings were effective at removing nitrogen from the wastewater. A second experiment determined the effects of adding a metal contaminated sludge on these same forage-corn interplantings, and on corn alone. Sludge applied at 7 metric tons per ha gave little increase in nitrate in the soil, but nitrate levels were increased at application rates of 22 t/ha. Corn yields were increased at all sludge application rates, with the most economic rate being 11 t/ha; the highest yields were obtained when the sludge application was repeated each year. Zinc, copper, and nickel levels increased in the groundwater after sludge application, but only zinc levels were raised in the corn grain. Sludge application rates of less than 54 t/ha do not appear to be a hazard either to the crop or to the groundwater. (Brambley-SRC)

LINING OF WASTE IMPOUNDMENT AND DISPOSAL FACILITIES.
Matrecon, Inc., Oakland, CA.
Environmental Protection Agency Report SW-870, September 1980. 406 p, 46 Fig, 48 Tab, 52 Ref, 9 Append.

Descriptors: *Lining, *Waste disposal, *Waste storage, *Leachates, Solid waste disposal, Water pollution prevention, Groundwater pollution, Land disposal, Sludges, Absorption, Soil sealants, Clays, Municipal wastes, Solvents, Bacteria.

The use of man-made materials of low permeability to line waste storage and disposal impoundments has been demonstrated to be a feasible method of preventing leachate and waste liquid components from leaking from an impoundment and subsequently entering and polluting groundwater. This manual is intended to provide information and guidance in the selection, performance, installation, and maintenance of specific liners and cover materials for specific containment situations, based upon the current state of the art of liner technology and other pertinent technologies. Wastes in lined facilities include: municipal solid waste, hazardous industrial wastes, and other nonradioactive and special wastes. The linings include remolded and compacted soils and clays, admixes, polymeric membrane liners, sprayed-on-liners, soil sealants, and chemisorptive liners. Liners function by two mechanisms: to impede the flow of the pollutant and pollutant carrier, usually water, into the subsoil and thence into the groundwater; or to absorb or attenuate suspended or dissolved pollutants in order to reduce the concentrations. From the standpoint of pollution and need for containment, it is the waste fluids which are of primary concern. The complexity of waste fluids, which include water, dissolved organic and inorganic components, organic chemicals and solvents, and bacteria, magnify the problems of containment. (Moore-SRC)

PHOSPHORUS DYNAMICS OF A FLORIDA FRESHWATER MARSH RECEIVING TREATED WASTEWATER,
Florida Univ., Gainesville. Center for Wetlands.
T. J. Dolan, S. E. Bayley, J. Zoltek, Jr., and A. J. Hermann.
Journal of Applied Ecology, Vol 18, No 1, p 205-219, April, 1981. 2 Fig, 7 Tab, 40 Ref.

Descriptors: *Phosphorus compounds, *Secondary wastewater, *Tertiary wastewater treatment, *Marshes, Nutrients, Fate of pollutants, Wastewater disposal, Wastewater treatment, Wetlands, Vegetation, Effluents, Florida, *Phosphorus removal, *Wastewater disposal.

Phosphorus in secondary effluent, applied weekly for a year to a test plot, was over 97% assimilated.

Soil (peat, clay, and sand) was the major sink, with secondary sinks in the below-ground biomass and litter. Three 2000 sq meter plots received effluent at the rates of 1.3, 3.8, and 10.2 cm per week, with a control plot receiving 3.8 cm per week of freshwater. Vegetation present included Sagittaria lancifolia, Pontederia cordata, Panicum spp. and Hibiscus sp. The plot with the highest rate of effluent loading showed increases in net production of plant shoots, litter, root and rhizomes, and in P concentration in living and dead plant tissue, compared with the control plot. There was 38.03 g P per sq meter applied to the high effluent plot during the course of the study; 26.31, 8.81, and 1.97 g P per sq meter were stored in soil, roots, and rhizomes, and litter, respectively. Outflow from the plot was 0.94 g P per sq meter. The freshwater control plot received a total of 0.38 g P per sq meter, stored 0.21 g P per sq meter in the litter, and lost 0.17 g P per sq meter in the outflow. There was no evidence of a spring flush of P from any plot. (Cassar-FRC)

ODOROUS COMPOUNDS FROM POTATO PROCESSING WASTE EFFLUENT IRRIGATION FIELDS: VOLATILE ACIDS,
Science and Education Administration, Berkeley, CA. Western Regional Research Lab.
R. G. Buttery, and J. A. Garibaldi.
Journal of Agricultural and Food Chemistry, Vol 28, No 1, p 158-159, January/February, 1980. 1 Fig, 2 Tab, 8 Ref.

Descriptors: *Organic acids, *Food processing wastes, *Odor control, Organic compounds, Acids, Pollutant identification, *Potatoes, Industrial wastes, Waste disposal, Irrigation.

When potato processing wastes are run into crop growing fields, an offensive odor can develop, especially under anaerobic conditions. The free acid fraction of the volatile oil isolated from odorous soil contained the following acids: acetic, propionic, isobutyric, butyric, 3-methylbutyric, pentanoic, hexanoic, and phenylacetic. Some of these acids were found at many times their odor threshold limit: butyric 90-1000 times, pentanoic 7-20 times, 3-methylbutyric 1-24 times, and isobutyric 100-1800 times. Odors may be decreased by encouraging aerobic conditions in the field by preventing pond formation (wider distribution and time interval for effluent application), increasing soil porosity, and ensuring high percolation rates of wastewater into the soil. (Cassar-FRC)

NITROGEN AVAILABILITY FROM SEWAGE SLUDGE,
Vermont Univ., Burlington. Dept. of Plant and Soil Science.
F. R. Magdoff, and J. F. Amadon.
Journal of Environmental Quality, Vol 9, No 3, p 451-455, July-September, 1980. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Sludge, *Land disposal, *Nitrogen, *Crop yield, Corn, Hay, Mineralization, Nitrification, Municipal wastes.

Application was made of aerobically treated secondary liquid sewage sludge to both corn and hay which were growing on Hadley sandy loam and Nellis loam soils. The nine treatments consisted of a check, four ammonium nitrate levels (50, 100, 150, and 200 kg N/ha/yr), and four sludge levels which were chosen to supply amounts of available N similar to the ammonium nitrate rates. Under laboratory conditions about 54% of the organic N added to the sludge-amended corn soils was mineralized. The mineralized N was well correlated with a chemical test of N availability. While the corn and hay on the sludge-amended Hadley soil outyielded the N treatments, nitrate recovery to 1.2 meters in the corn plots indicated that the available N supplied by the sludge treatments was no greater than that supplied by ammonium nitrate. Other factors, such as increased K supply to both crops and residual N effect on second-year hay, perhaps caused the increased yield of crops to sludge over N. Little or no response was noted in corn yields to sludge or N on the Nellis loam. Hay responded more to N than to sludge on the Nellis loam. Estimates of mineralization of organic N from sludge applied to corn and hay averaged 55% for the first year of application. Recovery of N in the corn at harvest plus soil NO3-N to a depth of 1.2 meters was positively correlated with the estimated mineralization of organic N plus the inorganic N added. The autoclaving test of N availability appeared useful in predicting mineralization of organic N from sludge under field conditions. (Baker-FRC)

SOIL AS A MEDIUM FOR DAIRY LIQUID WASTE DISPOSAL,
Southern Illinois Univ. at Carbondale. Dept. of Plant and Soil Science.
S-Y. Yang, J. H. Jones, F. J. Olsen, and J. J. Paterson.
Journal of Environmental Quality, Vol 9, No 3, p 370-372, July/September, 1980. 3 Tab, 13 Ref.

Descriptors: *Dairy industry, *Land disposal, Effluents, Industrial wastes, Animal wastes, Farms, Water pollution, Water quality, Biological oxygen demand, Phosphates, Nitrates, Suspended solids.

Attempts were made to determine a design for an effective vegetative-soil filter for liquid dairy waste disposal in relation to the highest loading rate per unit area of land under the most adverse climatic conditions, the filtering action of the vegetation, and the water quality if surface runoff during rainfall and snowmelt, and ground water. The soil used was classified as a Hosmer silt loam with an impermeable dense fragipan layer at the 50 cm depth. The experimental area was in tall fescue and had a 3% north facing slope with an intermittent stream at the lower end. Soil moisture and climatic conditions were important parameters affecting land application rates of dairy liquid waste. Large amounts of dairy liquid waste were absorbed and used by the soil and plants in the summer when evaporation and transpiration were high. The most critical period for loading was when the soil was wet or frozen, from the standpoint of controlling runoff pollution from effluent applications. The highest loading rate for zero surface runoff under the most adverse conditions was 0.43 cm/day. The pollutants in the dairy effluent were not effectively removed by flowing over the vegetative-soil filter. BOD5 decreased by 41%, ammonia nitrogen by 36%, suspended solids by 69%, and phosphate phosphorus by 16%. The most probable pollutants of runoff from rainfall and snowmelt were BOD5, ammonium-nitrogen, and phosphate-phosphorus. The field study showed a 99% decrease in BOD5 and a 90% removal of phosphate-phosphorus from the effluent by the soil. (Baker-FRC)

LEACHING OF CALCIUM AND MAGNESIUM FROM SOIL COLUMNS AS AFFECTED BY FORM OF NITROGEN IN APPLIED SEWAGE,
California Univ., Davis. Dept. of Land, Air, and Water Resources.
D. Pal, and F. E. Broadbent.
Soil Science Society of America Journal, Vol 45, No 1, p 56-60, 1981. 5 Fig, 8 Tab, 3 Ref.

Descriptors: *Leaching, *Land disposal, *Soil columns, *Calcium, Nitrogen, *Magnesium, Soil solution, Wastewater disposal, Soil profiles, Leachates, Nitrification, Denitrification.

Synthetic sewage containing elevated levels of nitrogen in either the ammonium or nitrate form was applied to soil columns at a rate of 7.5 centimeters per week for 41 weeks. Effluents from the column treated with ammonium sewage had higher concentrations of calcium and magnesium than did those from the column treated with nitrate sewage. When soil columns were treated with treatment plant sewage augmented by the addition of ammonium or nitrate to bring the nitrogen level to about 4 milliequivalents (meq) per liter, ammonium-amended sewage removed 1.32 meq more calcium and 0.84 meq more magnesium per liter of effluent than did nitrate-amended sewage. A third experiment involved application of unamended secondary waste water to columns of two different soils, one lot prior to nitrification and the other after nitrification had proceeded to completion. Calcium elution in Panoche clay loam was the same under both conditions, while magnesium elution was greater when the sewage was nitrified. In tests with Columbia fine sandy loam, somewhat more calcium and slightly less magnesium were eluted by nitrified sewage. When soils received sewages with artificially elevated concentrations of nitrogen, removal of calcium and magnesium were measurably higher when the ammonium form of sewage was applied. However, consistent differences between forms of sewage were not observed at the lower nitrogen levels characteristic of normal sewages. It is concluded that the influence of nitrification on solubility of calcium and magnesium under normal conditions is not sufficient to justify modification of wastewater management practices to prevent increasing the hardness of groundwater as long as the sewage contains normal levels of nitrogen. ANAEROBIC TREATMENT OF HUMAN WASTE IN NORTHERN COMMUNITIES,
Toronto Univ. (Ontario). Dept. of Civil Engineering.
G. W. Keinke, and D. Prasad.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 156-164, January, 1980. 4 Fig, 8 Tab, 25 Ref.

Descriptors: *Anaerobic digestion, *Waste disposal, *Cold regions, *Waste treatment, Wastewater treatment, Methane bacteria, Bacteria, Coliforms, Domestic wastes, Underground waste disposal, Canada, Permafrost.

A laboratory scale waste pit was operated for 5.5 years at temperatures simulating a human waste disposal pit in the permafrost of northern Canada. Treatment of the concentrated wastes (average COD 110,360 mg per liter) did not occur. At the end of the study coliform bacteria had decreased to negligible numbers, 10 per ml, but total aerobic and anaerobic bacteria remained at 80,000 per ml each, a potential hazard to public health and the environment. Anaerobic digestion of these wastes (called honey bag wastes) proved possible at 20 degrees C, but was uneconomical for these isolated communities. It was possible to process the more dilute black water wastes (average COD 10,210 mg per liter, from vacuum sewers, pressure sewers, or holding tanks) at 20 degrees C and a minimum detention time of 30 days. Operation at lower temperatures may be possible if a high proportion of methane bacteria is maintained in the reactor, either by longer detention time or by the anaerobic contact process. DISPERSAL OF ASPERGILLUS FUMIGATUS FROM SEWAGE SLUDGE COMPOST PILES SUBJECTED TO MECHANICAL AGITATION IN OPEN AIR,
Science and Education Administration, Beltsville, MD.
P. D. Millner, D. A. Bassett, and P. B. Marsh.
Applied and Environmental Microbiology, Vol 39, No 5, p 1000-1009, May, 1980. 4 Fig, 8 Tab, 22 Ref.

Descriptors: *Sludge, *Fungi, Wastewater, Aspergillus fumigatus, Composting, Atmosphere, Wind, Air pollution, Aerosols, *Fallout.

An aerometric survey was conducted to quantitatively characterize the airborne concentrations of Aspergillus fumigatus at a compost site. The study was conducted at a pilot-scale sewage sludge composting facility and two other selected test sites. Aerosols of A. fumigatus downwind from station-

ary compost piles were insignificant in comparison with those downwind from agitated piles. These aerosols were generated by a front-end loader moving and dropping compost. Aerial concentrations of the fungus at a distance downwind from the point of emission were used to determine an emission rate for A. fumigatus associated with the moving operations. The maximum emission rate, 4.6 million A. fumigatus particles per second, was used to calculate predicted concentrations in an unobstructed plume with restrictive, neutral, and dispersive atmospheric mixing conditions up to 1 km downwind from the emission source. While the dispersal tests were made only under a few different meteorological conditions, the results can be extended to a complete matrix of conditions by using the atmospheric dispersion model and statistical data from the National Weather Service. In evaluating the dispersal of microbial aerosols to locations around composting sites, the frequency distribution of meteorological factors, such as wind speed, wind direction, and atmospheric stability, which contribute to restrictive conditions, and which may be expected to occur in the subject locality, should be considered. COMPARATIVE ANALYSIS OF SLUDGE AND REFUSE LEACHATE: A PRELIMINARY REPORT,
Schneider Engineers, Bridgeville, PA.
D. S. Gilligan, and J. L. Pierce.
Public Works, Vol 112, No 5, p 89-93, May, 1981. 1 Fig, 3 Tab, 5 Ref.

Descriptors: *Landfills, *Sludge disposal, *Heavy metals, *Municipal wastes, Waste disposal, Land disposal, Pesticides, Color, Odors, Coliforms, Incineration, Leachates, *Allegheny County, Pennsylvania.

During the treatment of wastewater at the Allegheny County Sanitary Authority (ALCOSAN), Pennsylvania, several residual by-products are generated which require disposal, usually by landfill. About 60% of the dewatered sludge is incinerated to ash, which is sent to landfills, while the remainder is limed to a pH of 12-12.5 and co-disposed with municipal refuse to privately-owned refuse landfills. A year-long study was conducted to compare leachate characteristics of five simulated municipal sludge and municipal refuse landfill cells. Cells were placed in landfill strate comprising: cell 1, sewage sludge; 2, domestic refuse and sewage sludge in a 4:1 ratio; 3, domestic refuse alone; 4, limed sewage sludge; and 5, domestic refuse and limed sludge in a 4:1 ratio. Metal levels in leachate of cells 1, 2, 4, and 5 compared favorably with concentrations of cell 3, which contained refuse only. All levels of Pb, Cr, Cd, and Ag were 100 times less than extraction procedure toxicity levels. Cell 3 contained higher levels of total coliform, fecal streptococci, and fecal coliform than any of the other cells. No problems with color or odor occurred, and attraction of disease vectors (rodents, flies, etc.) was minimal in all the landfill sites. (Geiger-FRC)

STRATEGY FOR RADIOACTIVE WASTE DISPOSAL IN CRYSTALLINE ROCKS,
Geological Survey, Menlo Park, CA.
J. D. Bredehoeft, and T. Maini.
Science, Vol 213, No 4505, p 293-296, July 17, 1981. 6 Fig, 8 Ref.

Descriptors: *Radioactive waste disposal, *Crystalline rocks, *Groundwater pollution, Waste disposal, Granite, Barriers, Groundwater movement, Flow characteristics, Path of pollutants, Hydrology, Permeability, Saline water, Sedimentary rocks, Rocky Mountain Arsenal, Denver Basin, Illinois Basin, Maryland, Water pollution sources, Water pollution prevention, *Underground waste disposal.

The multiple barriers concept is used to evaluate possible sites for disposal of radioactive wastes. A satisfactory site would be a nonpermeable, crystalline rock mass (granite or gneiss) under a covering of sedimentary rocks whose groundwater flow characteristics are well understood. Under favorable circumstances the groundwater flow operates as an active barrier, preventing the pollutants from reaching the biosphere. In addition, the depository may be placed where groundwater is nonpotable or salty, minimizing the possibility of future human intrusion. Other barriers are the waste's form and encapsulation and a low-permeability, high-adsorption backfill. Sites having characteristics similar to those of the hypothetical situation are the coastal plain of Maryland, the Denver Basin Cretaceous shale sequence (except in areas of oil and gas production), and the Illinois basin. FINAL ENVIRONMENTAL IMPACT STATEMENT; SLUDGE DISPOSAL AND LAND RECLAMATION IN FULTON COUNTY, ILLINOIS.
Environmental Protection Agency, Chicago, IL. Region V.
Report, January, 1981. 330 p, 43 Fig, 48 Tab, 129 Ref, 3 Append.

Descriptors: *Environmental Impact Statement, *Fulton County, Illinois, *Land disposal, *Sludge disposal, *Land reclamation, Environmental effects, Runoff, Erosion control, Sedimentation, Water pollution, Soil physical properties, Agriculture, Recreation, Employment.

The Metropolitan Sanitary District of Greater Chicago is applying sludge to strip-mined land in Fulton County, and this Environmental Impact Statement presents the observed and projected impacts of continued operations. The sludge is transported by barge and underground pipeline to holding basins, where it is mixed to a uniform consistency and 6% solid content before being pumped into the distribution system. Originally the sludge was sprayed onto the land, but following complaints of odor, the sludge is now disked into the soil. This method also decreases runoff and erosion problems. Some runoff has occurred and some of the retention basins were too small to allow effective siltation. There have been breaks in the sludge pipelines, resulting from expansion and contraction from changes in temperature, which have caused violations of water quality standards. The physical properties of the soils have improved and crop productivity has increased. Former agricultural land has been put back into use for agricultural and recreational uses. No adverse health effects have been reported, and they will be prevented by appropriate agricultural use of the land. The project has given employment to about 120 persons for 6-8 months each year. (Brambley-SRC)

STATE-OF-THE-ART OF LIQUID WASTE DISPOSAL FOR GEOTHERMAL ENERGY SYSTEMS: 1979,
Battelle Pacific Northwest Labs., Richland, WA.
L. J. Defferding.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV-0083, Price codes: A12 in paper copy, A01 in microfiche. Department of Energy Report DOE/EV-0083, June 1980. 252 p, 23 Fig, 12 Tab, 133 Ref, 3 Append. DE-AC06-76RLO 1831.

Descriptors: *Geothermal resources, *Resources development, *Wastewater disposal, *Liquid wastes, Injection wells, Evaporation pans, Surface water, Wastewater treatment, Legal aspects, Environmental effects, Economic aspects, Waste characteristics.

As geothermal resources are developed as energy sources, safe disposal methods must be found for the large volumes of wastes. Techniques currently in use are direct discharge into surface waters, deep-well injection, and ponding for evaporation. Additional techniques with little or only experimental use are treatment and release to surface water, consumptive secondary use, injection into a non-producing horizon, and treatment and injection. All the disposal methods have to be considered in relation to the technical, legal, environmental and safety aspects, and to their overall economics. Other considerations are the variability of the waste fluid properties and the site-specific variables of geology and environmental setting. With present legal and environmental constraints subsurface injection is the most popular disposal method, but it is an expensive method, there have been technical problems with equipment, and some treatment will probably be necessary. (Brambley-SRC)
W82-00375

ENGINEERING ASSESSMENT OF VERMICOMPOSTING MUNICIPAL WASTEWATER SLUDGES,
Camp, Dresser and McKee, Inc., Boston, MA.
J. Donovan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-196933, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-075, June 1981. 4 p, 1 Tab.

Descriptors: *Composting, *Sludge disposal, Vermicomposting, *Biological treatment, Economic feasibility, Municipal wastewater, Organic matter, *Biodegration, *Earthworm feeding.

Vermicomposting, the biological degradation of organic matter that occurs as earthworms feed on waste materials, has been advocated by some as a means of stabilizing and disposing of municipal wastewater sludges. Only two species of earthworms, Eisenis foetida and Lumbricus rebellus are commonly mentioned in the literature as suitable for use in waste-vermicomposting operations. These worms can thrive and reproduce in managed conditions and readily feed on high concentrations of organic matter. When these worms are added to shallow beds or windrows of sewage sludge, they feed on the sludge, digest a portion of the organic matter and expel the undigested remains as feces, or castings. The castings produced by worms that have been fed on sludge are dry, virtually odorless, and suitable for use as a soil amendment or low-order fertilizer. Based on review of available literature, dicussion with practitioners, and visits to sites where vermicomposting is being attempted on an experimental scale, the process has been found to be feasible and potentially competitive economically with conventional sludge stabilization techniques such as land spreading of liquid sludge and static pile composting. (Moore-SRC)

LIME STABILIZATION AND ULTIMATE DISPOSAL OF MUNICIPAL WASTEWATER SLUDGES,
Camp, Dresser and McKee, Inc., Boston, MA.
R. M. Otoski.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-198160, Price codes: A09 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-076, June 1981. 4 p, 2 Fig, 1 Tab.

Descriptors: *Lime, *Sludge disposal, *Wastewater treatment, *Sludge conditioning, Land disposal, Municipal wastewater, Hydrogen ion concentration, Odor control, Pathogens.

The process of lime stabilization involves adding lime to wastewater-derived sludge in quantities sufficient to raise the pH of the sludge to 12.0 for a contact period of at least 2 hours. The high pH reduces levels of pathogenic bacteria and viruses in the sludge and controls putrefaction and orders. Visits were made to 28 wastewater treatment facilities in New England and New York at which lime stabilization of sludge was reportedly being practiced on a permanent, interim or seasonal basis. In fact, true stabilization was not achieved at some of the plants visited; several routinely limed sludge to

UBRARY U. OF ILL. URBANA-CHAMPAIGN

pH levels slightly below 12. Sludge stabilization with lime can be simple and inexpensive and can be used as a backup or interim system, or to upgrade a system, or instituted as a less costly system. The only lime stabilization method rated fully acceptable is the addition of lime to mixed batch tanks. Adding lime before dewatering with the use of equipment intended for sludge conditioning requires close operator attention. Adding lime directly to dewatered sludge cake has not yet been consistently effective in bacterial kills. Stockpiling provides flexibility in land-application schedules, but if pH drops, bacteria can regrow in the stockpiles. (Moore-SRC)

DEEP WELL INJECTION OF INDUSTRIAL WASTES,
A. S. Athavaley, R. J. Funk, R. G. Sweet, and W. A. Coffey.
Industrial Wastes, Vol 27, No 3, p 28-30, 33-34, May/June, 1981. 3 Fig, 2 Tab.

Descriptors: *Injection wells, *Oil industry, Industrial wastes, *Underground waste disposal, Acidic water, Wastewater treatment, Wastewater disposal, Corpus Christi, Texas.

Spent caustic from an olefins plant at Corpus Christi, Texas represents a problem wastewater stream for disposal. The concentration of the caustic can range from two to five percent. The wastewater pH is expected to run consistently at about 13. The sulfide content may range from 500 to 35,000 mg/liter. About 50,000,000 gallons of wastewater will have to be disposed of annually when the plant is in full operation. This represents a design average flow rate of about 100 gpm, with minima and maxima ranging from 40 to 100 gpm, respectively. The wastewater cannot be discharged to any watercourse due to its toxic and refractory characteristics. Treatment for surface disposal is not economically feasible, due to the tight restrictions imposed on levels of total organic carbon and chemical oxygen demand. A disposal well system for handling the caustic wastewater has been designed with a 20 year project life. It was designed to comply with regulations of the various government branches of Texas and the federal government as well. Both an operational and a standby disposal well were drilled, to give a combined, firm capacity of 200 gpm. Because the wastewater was incompatible with the reservoir formation water, it was necessary to develop a buffer placement program, which is a one-time operation. This prevents the formation of precipitates when the formation water component is contacted by the wastewater and provides a barrier which delays contact between injected wastewater and formation water. This helps avoid plugging of the injection well with precipitates. (Baker-FRC)

EFFECTS OF MOISTURE CONTENT ON LONG-TERM SURVIVAL AND REGROWTH OF BACTERIA IN WASTEWATER SLUDGE,
BDM Corp., Albuquerque, NM.
J. G. Yeager, and R. L. Ward.
Applied and Environmental Microbiology, Vol 41, No 5, p 1117-1122, May, 1981. 4 Fig, 10 Ref.

Descriptors: *Moisture content, *Sludge, *Enteric bacteria, Bacteria, *Wastewater treatment, Liquid sludge, Sewage bacteria, Survival, Population density, Population dynamics, *Sludge drying.

Although long-term storage is often used for pretreatment of wastewater sludge prior to land application, little is known about the effects of this form of treatment on the numbersof bacterial pathogens in sludge. The effects of moisture content of sludge on the inactivation rates of bacteria during long-term storage and on bacterial regrowth potential were investigated. Cultures of six strains of fecally associated bacteria grown in sterilized liquid sludge (5% solids) were all quite stable at this moisture level for over 90 days at 21C. Bacterial inactivation rates following evaporation occurring during long-term storage at this temperature were generally proportional to the moisture losses of the samples. However, in dried sludge containing more than 90% solids, all but one of the bacteria species studied were found to be extremely stable. Bacteria indigenous to sludge were also found to survive for long periods in dried sludge. Bacteria isolates in sterilized raw sludge were found to undergo regrowth rapidly at 37 degrees C in samples containing not more than 75% solids, but no regrowth occurred in samples containing more than 85% solids. Although seeded Salmonella typhimurium grew in the presence of indigenous bacteria in both liquid and dewatered raw sludges, the population densities attained were well below that found in sterilized samples of the same sludges. While the number of salmonella dropped below detectable limits within a few days in sludges containing viable indigenous organisms, little decrease occurred during this time with salmonella grown in previously sterilized sludges. EFFECTS OF SEWAGE EFFLUENT APPLICATION ON LITTER FALL AND LITTER DECOMPOSITION IN CYPRESS SWAMPS,
Florida Univ., Gainesville. School of Forest Resources and Conservation.
G. S. Deghi, K. C. Ewel, and W. J. Mitsch.
Journal of Applied Ecology, Vol 17, No 2, p 397-408, August, 1980. 4 Fig, 5 Tab, 28 Ref.

Descriptors: *Swamps, *Land disposal, *Litter, Organic matter, Wastewater, Effluents, Decomposition, *Florida, *Wetlands, Forests, *Cypress swamps, Wastewater treatment.

Cypress domes, which are characteristic of ecosystems in Florida, are stillwater swamps dominated by pond cypress. The adaptation of vegetation and soils in cypress domes to saturated conditions and the absence of overland flow to other bodies of water has resulted in consideration of these sites for recycling of secondarily treated sewage effluents. The ability of cypress domes to absorb the nutrients and microbes in these effluents and the effects of treatment with sewage effluents on litter production and decomposition rates were studied at four sites in Florida over a two-year period. Although no increases in litter fall attributable to treatment with sewage effluent were found in the experimental domes, data from other studies indicates that this rate may increase. Phosphorus cycling in the cypress domes seemed to be speeded by treatment with effluent and with groundwater. The lower concentration of oxygen in the sewage treated domes did not hinder the decomposition process. Decomposition of cypress needles occurred more rapidly in wet areas than in dry sites, but there was no difference in decomposition rates between deep and shallow wet sites. Biomass losses appear to be dependent on temperature and moisture. Decomposition may proceed more rapidly in domes treated with sewage effluent than in untreated domes as a result of the increased nutrient levels in the substrate. Since increases in litter fall do not result in decreases in the decomposition rate, application of sewage effluent should not result in an increase in the normal accumulation of organic matter in the domes until a new steady-state level is reached. 5F. Water Treatment and Quality Alteration

CHEMICAL, PHYSICAL, AND RADIOLOGICAL QUALITY OF SELECTED PUBLIC WATER SUPPLIES IN FLORIDA, FEBRUARY-APRIL 1980,
Geological Survey, Tallahassee, FL. Water Resources Div.
B. J. Franks, and G. A. Irwin.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-227910, Price codes: A04 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-31, 1981. 59 p, 4 Fig, 6 Tab, 13 Ref.

Descriptors: *Potable water, *Water quality, *Water supply, *Water treatment, Water quality standards, Water analysis, Chemical analysis, Surface water, Groundwater, Desalination, *Florida, Drinking water, Regulations.

Virtually all treated public water supplies in Florida meet the National Interim Primary and Secondary Drinking Water Regulations. These findings are based on a water-quality reconnaissance of 126 raw and treated public water supplies throughout the State during the period February through April 1980. Primary drinking water regulations maximum contaminant levels were rarely exceeded, although mercury (1 site), fluoride (2 sites), and radionuclides (3 sites) in water supplies were above established maximum contaminant levels. Dissolved solids, chloride, copper, manganese, iron, color, sulfate, and pH, were occasionally slightly in excess of the recommended maximum contaminant levels of the secondary drinking water regulation. The secondary regulations, however, pertain mainly to the esthetic quality of drinking water and not directly to public health aspects. (USGS)

PROCESS FOR THE REMOVAL OF INORGANIC SALTS FROM A WATER STREAM,
D. W. Coillet.
U.S. Patent No. 4,234,419, 11 p, 1 Fig, 1 Tab, 5 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1104-1105, November 18, 1980.

Descriptors: *Patents, *Water treatment, *Industrial water, Wastewater treatment, Water purification, *Ion exchange, Chemical precipitation, Brine disposal, Byproducts, Potable water, Salt removal, Dissolved solids, Regeneration.

Inorganic salts are removed from an unpotable water stream, particularly a salt-containing inland water stream. Such waters include ground water, including geothermal brine, waste waters, including field drainage and urban waste water, and aqueous waste from the operation of evaporative cooling towers and certain processes of industry and energy conversion. The stream is passed sequentially through anion and cation exchange beds. Periodically the anion exchange bed is regenerated with sodium hydroxide and the cation exchange bed with hydrochloric acid to form spent regenerant streams which are combined with hydrochloric acid in the presence of calcium ion to precipitate calcium salts of anions from the mixture. The soluble portion is then mixed with sodium hydroxide in the presence of carbonate ion to precipitate insoluble cations from the mixture as hydroxides or carbonates. The soluble portions, comprising essentially an aqueous sodium chloride stream, is separated into a more concentrated and less concentrated portion. The more concentrated stream is electrolzed to provide a source of hydrochloric acid and sodium hydroxide for the above steps, while the less concentrated stream is recovered as a source of potable water. (Sinha-OEIS)
W82-00055

FLUORIDATION SYSTEM,
J. N. Leo.
U.S. Patent No. 4,234,425, 4 p, 2 Fig, 8 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1107, November 18, 1980.

Descriptors: *Patents, *Water treatment, *Fluoridation, Public health, Equipment, Flow control, Venturi meters.

A fluoridation system includes a venturi capable of being inserted into a water line along its length.

The venturi includes a throughbore having a diminishing tapered section followed by an increasing tapered section in the direction of liquid flow and a passage which intersects the throughbore perpendicularly. A mechanism associated with the venturi withdraws water from the water line and a first conduit for transferring water from the withdrawing mechanism contains a flow rate measurer and flow control. The fluoride chamber is connected to the outlet end of the first conduit, and a second conduit connects the fluoride chamber with the perpendicular passage of the venturi. (Sinha-OEIS)
W82-00061

PROCESS FOR REMOVING ALKALINITY AND HARDNESS FROM WATERS,
Water Refining Co., Inc., Middletown, OH. (Assignee).
R. E. Wiegert.
U.S. Patent No. 4,235,715, 6 p, 2 Fig, 13 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 4, p 1531, November 25, 1980.

Descriptors: *Patents, *Water treatment, *Water quality control, *Hardness(Water), *Alkalinity, Separation techniques, Industrial water, Ion exchange, Resins, Cation exchange, Chemical reactions, Boiler feed water, Regeneration.

Raw water is fed to a first column containing a weak acid cation exchange resin in hydrogen form where alkalinity causing ions and hardness causing ions to the extent of alkalinity are converted to carbonic acid. The carbonic acid, which hydrolyzes to dissolved carbon dioxide, is stripped from the water in a decarbonation unit by passing air countercurrent to the flow of water through the unit. The water is then fed to a second column containing a weak acid cation exchange resin in sodium form which removes residual hardness causing ions along with neutralization of any mineral acids or residual dissolved carbon dioxide. Both resins are substantially completely regenerated upon exhaustion to provide a process in which the maximum capacities of the resins are utilized, and the process is carried out with a minimum of monitoring and control. In terms of operating and investment costs, it is much more economical to treat raw feed water to remove hardness and alkalinity prior to introducing it into equipment. (Sinha-OEIS)
W82-00063

A/C PIPE - ASSESSMENT OR ADVOCACY,
A/C Pipe Producers Association, Arlington, VA.
J. F. Welch.
Water/Engineering and Management, Vol 128, No 5, p 44, 48, 54, 57-58, May, 1981. 1 Fig, 1 Tab, 29 Ref.

Descriptors: *Asbestos, *Asbestos cement, *Public health, *Drinking water, Water quality, Pipes, *Pipelines, Water transport, Water mains, Carcinogens, Evaluation.

A commentary is presented on the issue of asbestos in drinking water, with emphasis on the assessment of the safety of asbestos-cement (A/C) pipes. While it is known that asbestos-cement pipe will corrode, the extent has not been determined to which people are affected by this corrosion. No one knows exactly how many miles of A/C pipe are exposed to corrosive waters or what levels of asbestos in water are dangerous to people. Airborne asbestos has been known to cause health effects in exposed workers, but there is little scientific information on the effects of asbestos ingestion by man or laboratory animals. It is not known whether asbestos fibers cross the intestinal tract. There are no animal studies or epidemiological studies linking asbestos ingestion to cancer, and several studies have indicated that there is no cancer hazard. More research is needed before realistic water quality criteria can be set for asbestos fibers. (Small-FRC)

AN ALTERNATIVE SOLUTION TO THE THM PROBLEM,
Dallas City Manager's Office, TX.
I. M. Rice, and M. E. Bolding.
Water/Engineering and Management, Vol 128, No 5, p 59-60, 65-66, May 1981. 6 Tab.

Descriptors: *Trihalomethanes, *Drinking water, *Ammonia, *Pilot plants, Chlorination, Chlorine, Hydrogen ion concentration, Activated carbon, Water supply, Dallas, Texas.

Pilot plant studies evaluated the extent to which trihalomethane formation in drinking water could be reduced by reducing the ammonia content of prechlorinated water. Tests were undertaken using three levels of chlorine, three different pH values, and operations with or without ammonia present. The pentane extraction method was used for all trihalomethane tests. Results indicated that advance ammonia feed could reduce trihalomethane formation without sacrificing good bacterial water quality. Coliforms were uniformly removed from the treated water in every case where ammonia was employed. Application of ammonia followed by addition of chlorine at the intake to the plant was more effective in preventing THM formation than application of chlorine at later stages. There were daily and weekly fluctuations in precursor content. Thus, trihalomethanes in drinking water can be reduced without the installation of granulated activated carbon treatment. These studies were performed on water from the Dallas, Texas system. (Small-FRC)
W82-00072

HISTORY OF A WATER CHEMICAL,
R. W. Ockershausen.
Water/Engineering and Management, Vol 128, No 5, p 73-75, May, 1981. 1 Fig.

Descriptors: *Alum, *Aluminum sulfate, *Clarification, Chemical precipitation, *Water treatment, Drinking water, History, Phosphorus removal.

The history of the use of alum, aluminum sulfate, in water treatment is presented. One hundred years ago alum saw continuous daily use at the Somerville and Raritan Water Company in the New Jersey water filtration plant, and there is evidence that this chemical has been used for centuries to clarify water. Lump alum was popular at the turn of the century, and ground or granular alum came into use in the 1920's. Liquid alum became available in the 1940's and both liquid and dry are used today. Alum continues to be the major coagulant used in water and wastewater treatment. It can be used for clarification, phosphorus reduction, and impurity removal. Dry alum requires more manufacturing steps, so liquid is the least expensive. This factor is making it more popular during today's inflationary times. Raw materials of domestic origin give assurance that supplies will be plentiful in the future. (Small-FRC)
W82-00074

DISTRIBUTION AND BALANCE OF VOLATILE HALOGENATED HYDROCARBONS IN THE WATER AND AIR OF COVERED SWIMMING POOLS USING CHLORINE FOR WATER DISINFECTION,
Bremen Univ. (Germany, F.R.).
U. Lahl, K. Batjer, J. V. Duszeln, B. Gabel, and B. Stachel.
Water Research, Vol 15, No 7, p 803-814, July, 1981. 6 Fig, 10 Tab, 42 Ref.

Descriptors: *Swimming pools, *Public health, *Chlorination, Trihalomethanes, Chloroform, Water treatment, Disinfection, Organic compounds, Recreation, Ozonation, Ultraviolet radiation, Chlorinated hydrocarbons, *Fate of pollutants, *Indoor swimming pools.

Chlorination of water in covered swimming pools in Bremen, Germany, produced trihalomethanes (THM) (largely CHCl3, CHCl2Br, CHClBr2, and CHBr3) at total concentrations up to 1224 micrograms per liter. Comparing THM concentrations in inflow and outflow showed that there was a 20-30% increase after five hours. THM formation depended on the amount of free active Cl, concentration of organic precursors (fulvic acids, humic acids, urine), concentration of other compounds reacting with Cl, concentration of Br ions, and number of pool visitors. After water treatment methods were refined (less chlorine, elimination of surface waters as a source, more fresh water added) the total THM levels dropped from 800 micrograms per liter in December 1978 to about 100 micrograms per liter in February 1979 and remained at that level. The concentration of THM found in air above the pools varied widely with location and distance above the water surface; the highest measured level was 384 micrograms per cu meter, and the average 0.1 micrograms per cu meter. The maximum cancer risk, based on chloroform, was calculated at 1 cancer event per million visitors per year for weekly visits in a covered pool in Bremen. Alternative disinfection methods include ultraviolet radiation and indirect ozonation. (Cassar-FRC)

REACTIONS OF CHLORINE WITH SELECTED AROMATIC MODELS OF AQUATIC HUMIC MATERIAL,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
D. L. Norwood, J. D. Johnson, R. F. Christman, J. R. Hass, and M. J. Bobenrieth.
Environmental Science and Technology, Vol 14, No 2, p 187-190, February, 1980. 4 Fig, 2 Tab, 21 Ref.

Descriptors: *Chlorination, *Humic acids, Natural waters, Chloroform, Drinking water, Disinfection, Water treatment, Chemical reactions, Hydrocarbons, Decomposing organic matter.

Chloroform yields and chlorine demands were measured for structures representative of humic degradation products and to identify in selected cases other chlorinated end products. Several compounds designed to model the monomeric components of aquatic humic material were reacted with aqueous chlorine at pH 7. Chloroform production and chlorine demand were measured for each compound over varied time periods. All compounds studied produced measurable amounts of chloroform with resorcinol derivatives showing the greatest yields. In addition, the chlorination reactions of resorcinol and 3-methoxy-4-hydroxycinnamic acid were studied in depth with GC/MS. The resorcinol reaction was found to proceed through several chlorinated intermediates, of which the most abundant was 3,5,5-trichlorocyclopent-3-ene-1,2-dione, to chloroform and chlorinated acids. Chlorination of the cinnamic acid derivative produced chlorinated substitution products and chlorophenols, which broke down upon further reaction to chloroacetic acids. (Baker-FRC)

HYGIENE OF DRINKING WATER IN DEVELOPING COUNTRIES,
Amsterdam Water Works (Netherlands).
C. van der Veen.
Aqua, No 5, p 2-7, 1980. 4 Tab, 21 Ref.

Descriptors: *Developing countries, *Drinking water, *Rural areas, *Water treatment, Water quality control, Potable water, Human diseases, Public health, United Nations, Organoleptic properties, Water supply, Water quality.

The provision of safer drinking water supplies in developing countries is considered. Water-related diseases which pose problems of hygiene may be classified as waterborne diseases, water-washed diseases, water-based diseases, and diseases with related insect vectors. The relationships between a nation's availability of a good water supply and the health standard of its people are illustrated in data from various countries. Differences in methods of water procurement from urban and rural areas are mentioned, and technologies associated with spring water, groundwater, roof drainage and ground catchment, surface water, and artificial recharge are explored. Often attempts to supply public water to rural areas fail due to a lack of education of the users. Old water sources may serve holy functions, provide a place of social gathering, and are more familiar in taste to the native populations.

LIBRARY OF THE URBANA-CHAMPAIGN

Some people may use public water only intermittently, so that disease conditions still exist. Often, the people are too poor to pay for public water and therefore they discontinue using it. Water projects should be financially self supporting. In 1977, the United Nations (UN) launched a Water Decade which set as its goal the provision of adequate supplies of quality drinking water for all people and the proper disposal of waste waters by 1990. UN figures indicated that in 1975, 62% of the populations of developing countries were not served by safe water supplies. The International Water Supply Association (IWSA) has appointed a task force which plans to stimulate the water supply authorities in developing countries by availing them of the knowledge of present technologies. THE EFFECT OF BENTONITE CLAY ON OZONE DISINFECTION OF BACTERIA AND VIRUSES IN WATER,
Environmental Protection Agency, Atlanta, GA.
D. S. Boyce, O. J. Sproul, and C. E. Buck.
Water Research, Vol 15, No 6, p 759-767, 1981. 1 Fig, 7 Tab, 23 Ref.

Descriptors: *Viruses, *Bacteria, *Ozone, *Bentonite, *Disinfection, Wastewater renovation, Wastewater treatment, Coxsackie virus, Polio virus, Escherichia coli, Bacteriophage, *Clays, Water treatment, Pathogens, Turbidity, Adsorption.

The disinfection potential of ozone for viruses and bacteria adsorbed on bentonite clay particles suspended in water was determined. Viruses used were poliovirus (Sabin Type 1), coxsackievirus A9, and the f2 bacteriophage. Escherichia coli was treated under the same conditions as the virus--unadsorbed or adsorbed on 1 and 5 turbidity units (TU) of bentonite clay (particle size 3-8 mm), up to 0.53 mg per liter ozone, temperature 20 C, pH 7.0, and inactivation times of 10, 20, and 30 sec. Poliovirus, coxsackievirus, and E. coli associated with clay were inactivated at rates similar to the freely suspended organisms. The f2 bacteriophage was inactivated at a slightly slower rate than freely suspended phage. Typical results obtained were: 5 TU adsorbed poliovirus (140 plaque forming units (PFU) per ml), 0.016 mg per liter ozone, > 97% inactivated within 20 sec; 5 TU adsorbed coxsackievirus (220 PFU per ml), 0.019 mg per liter ozone, > 98% inactivated within 20 sec; 5 TU adsorbed f2 bacteriophage (15,000 PFU per ml), 0.061 mg per liter ozone, > 98% inactivated within 20 sec; 5 TU adsorbed E. coli (180 million CFU per ml), 0.038 mg per liter ozone, > 99% inactivated within 10 sec. A 13-MONTH SURVEY OF NEMATODES AT THREE WATER TREATMENT PLANTS IN SOUTHERN ONTARIO, CANADA,
Waterloo Univ. (Ontario). Dept. of Biology.
J. B. Mott, G. Mulamoottil, and A. D. Harrison.
Water Research, Vol 15, No 6, p 729-738, 1981. 7 Fig, 3 Tab, 38 Ref.

Descriptors: *Drinking water, *Nematodes, *Water treatment, Aquatic animals, *Canada, Settling basins, Turbidity, Rainfall, Chlorination, Seasonal variation, River flow.

Nematodes were detected in almost every sample of treated water from three Canadian cities during a 13-month survey. In general, numbers at Brantford were lower (0 to 5.6 per liter) than at Cayuga (maximum 42.5 per liter) and Delhi (maximum 38.7 per liter). Brantford has the largest facility and most extensive water treatment (prechlorination, coagulation, settling, rapid sand filtration, postchlorination, and fluoridation). The water source is a slow-moving canal leading from the Grand River. At Cayuga and Delhi, water treatment is less extensive (coagulation, chlorination, and sand filtration). Water sources are direct from the Grand River and the North Creek, respectively. Nematode concentrations increased with high river flow, heavy rainfall, and high raw water turbidity. Lowest concentrations were found during the winter months. A settling tank or pond for raw water and high levels of prechlorination are recommended to reduce nematode counts. (Cassar-FRC)

CUTTING THE WATER LOSSES,
Northumbrian Water Authority, Gosforth (England).
B. Smith.
Water, No 33, p 2-4, July, 1980. 1 Fig.

Descriptors: *Water conveyance, *Leakage, *Maintenance, Water supply systems, Economic aspects, Technology, Reservoirs, Water mains, Pipes, Conveyance structures, *Great Britain.

There has been increasing public concern regarding leakage control policies of water supply systems in Great Britain as a result of increased opposition to the development of new water supply sources, particularly those involving the construction of impounding reservoirs. There are five main leakage control methods: passive leakage control (repairing only leaks which become self-evident), regular sounding, district metering with selective inspection, waste metering with selective inspection, and combined district and waste metering with selective inspection. Although the formation of pressure zones can be used with each of these control methods, there is no clear information on the magnitude of leakage reduction which can be expected from a specific reduction in pressure. Selection of the most economic leakage control measure in a given situation will be affected by such factors as the cost of producing water, the need for pumping, financial contraints, topography, and the overall extent of the leakage problem. The British Working Group on Waste of Water has developed a comprehensive procedure for determining a leakage control policy for any system, irrespective of current practice, in which the relevant local factors and constraints are considered. TREATMENT WORKS--THE DESIGNER'S PROBLEMS,
Hill (G. H.), Manchester (England).
P. B. Connery, and J. B. Butler.
Water, No 30, p 7-9, January, 1980.

Descriptors: *Water treatment facilities, *Design criteria, *Planning, Site selection, Water treatment, Economic aspects, Monitoring, Water pollution control, Water quality management, Design standards.

Designers are responsible for the integration of the various treatment processes, structures, and equipment into a water treatment facility which will enable the operator to produce water or effluent of the required quality efficiently. Important aspects which the designer must consider include selection of the site, raw water parameters, standards for treated water quality, and type of facility required. Factors impacting on site selection include proximity to sources of treatable water and to users, elevation, site ground conditions, site topography, distance from chemical supply sources, and access for delivery vehicles. Energy conservation is playing an increasingly important role in site selection decisions. The development of information on sources of water likely to be exploited is creating a better basis for the evaluation of the raw water conditions which may be expected. Changing standards for treated water quality raise questions as to whether designs for new plants should include allowances for possible addition of other treatment processes at a later time. The inclusion of raw water storage facilities can significantly reduce the range of the quality of the water to be treated and can simplify treatment. The rapid advance of technology in water treatment also raises questions concerning the design life of facilities. Treatment facilities' designs should be flexible enough to permit expansion as additional capacity is needed and incorporation of additional processes or innovations at a future date. Controls should be selected to be compatible with the quality of monitoring available. (Carroll-FRC)

MATHEMATICAL EFFICIENCY CONCERNS IN WATER DISTRIBUTION NETWORK CONSIDERATIONS,
Waterloo Univ. (Ontario). Dept. of Civil Engineering.
S. Gupta, E. A. McBean, and J. R. Cousins.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 78-83, 1980. 6 Fig, 2 Tab, 18 Ref.

Descriptors: *Network design, *Computer models, *Design criteria, *Water distribution, Mathematical models, Water supply systems, Comparison studies.

A comparison of three computerized methods for analyzing water distribution systems shows that the Newton-Raphson technique has a slight advantage over the Hardy-Cross method. Total costs of all three models in a 22-node system are about $30; for 68 nodes, about $60 for the Newton-Raphson and Hardy-Cross methods, and $135 for the linear algebra technique. To decrease modeling costs, schematization models representing the same network, but with fewer nodes, may be used for design studies, which require many repetitive runs. (Cassar-FRC)
W82-00339

SILICATES AS NONSPECIFIC ADSORBENTS OF BACTERIOPHAGE: A MODEL FOR PURIFICATION OF WATER FROM VIRUSES,
Israel Inst. for Biological Research, Nes Ziyyona.
R. Fass, Y. Straussman, A. Shahar, and A. Mizrahi.
Applied and Environmental Microbiology, Vol 39, No 1, p 227-232, January, 1980. 1 Fig, 4 Tab, 16 Ref.

Descriptors: *Water treatment, *Viruses, Purification, Drinking water, Potable water, Wastewater, *Silicates, Bacteriophages, Adsorbents.

Commerically available amorphous silicates having small size particles, large surface areas, and high adsorption capacity for organic compounds were investigated as virus adsorbents. The T4 bacteriophage was used in this study as a model due to its well-defined morphology and its stability towards agitation and temperature changes, as well as due to the availability of a convenient assay. Amorphous silicates were found to have a high nonspecific adsorption capacity for T4 bacteriophage, representing a promising tool and a model for purification of water from viral contamination. Investigations with Escherichia coli T4 bacteriophage showed adsorption capacity of up to 99.9% on different tested silicates. Optimal conditions for the adsorption of T4 bacteriophage on various commercially available silicates were determined. A continuous-flow adsorption of T4 bacteriophage on silicates appears to represent a model system for the removal of viruses from potable water and sewage. (Baker-FRC)

FIELD EVALUATION OF A SWIRL DEGRITTER AT TAMWORTH, NEW SOUTH WALES, AUSTRALIA,
G. J. Shelley, P. B. Stone, and A. J. Cullen.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187247, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-063, June 1981. 6 p, 2 Fig, 5 Ref.

Descriptors: *Water treatment, *Suspended solids, Field tests, *Pretreatment of water, Suspended load, Particle size, Flow rates, Cost analysis, Hydraulic engineering, Construction costs, Operating costs, Maintenance costs, New South Wales, *Australia.

The overall objective of this field evaluation program was to provide information on the behavior of a full-scale swirl degritter designed and constructed in accordance with the shapes and proportions developed during model studies. The swirl degritter was designed to pretreat river water before it enters into the rising main in order to reduce wear and tear on the raw water pumps and also to reduce the solids loading of the rising main and that of the balance tank of the water treatment works. Results of the solids removal had been evaluated in terms of three parameters: solids larger than 0.2 mm (the classical size aimed at in grit chambers); solids larger than 0.088 mm; and total settleable solids. In general, the tests proved the validity of the laboratory results, and at design flowrates, 98% removal efficiencies were achieved. Tests at flowrates higher than the design showed slightly better efficiencies than predicted. The field evaluation tests carried out at Tamworth, New South Wales, Australia, prove the validity of the system in terms of its hydraulic efficiency. When compared with a conventional, constant-velocity, longitudinal flow grit chamber, the construction cost is halved and operation and maintenance costs are considerably lower. (Author's abstract)
W82-00376

EFFECTIVENESS OF ACTIVATED CARBON FOR REMOVAL OF TOXIC AND/OR CARCINOGENIC COMPOUNDS FROM WATER SUPPLIES,
Michigan Univ., Ann Arbor.
W. J. Weber, Jr., and M. Pirbazari.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187197, Price codes: A17 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-057, June 1981. 9 p, 11 Fig.

Descriptors: *Water treatment, *Activated carbon, Adsorption, Chlorinated hydrocarbons, Humic acids, Organic matter, Model studies, Biological degradation, Water supply, *Toxins, *Carcinogens, Magnesium, Calcium, Polychlorinated biphenyls, Benzenes, Dieldrin, Carbon tetrachloride.

Equilibrium, rate and continuous long-term adsorption studies were conducted for humic acids at raw water background concentrations and for carbon tetrachloride, benzene, two commercial mixtures of PCB's, dieldrin, and p-dichlorobenzene at representative trace concentration levels. Experimental breakthrough profiles were developed for each of the trace compounds alone and in the presence of background humic acid solutions to investigate competitive and/or chromatographic effects. The results indicate that trace compound adsorption is generally affected adversely by background organic matter. The adsorption capacity of activated carbon for humic substances was markedly enhanced by the presence and concentration of several common constituents of water supplies, including Mg and Ca ions. There was evidence from the work that enhanced removal of humic substances might also provide for more effective removal of associated organic molecules - such as PCB's and dieldrin - in water treatment operations. The Michigan Adsorption Design and Applications Model (MADAM) was generally able to simulate and predict the performance of fixed-bed adsorbers to remove the compounds investigated in the absence of the humic acids. With the strictly adsorption version of MADAM, reliable predictions were difficult because of the prolific biological growth in the adsorbers that received the humic acids. For such cases, biological degradation dynamics must be incorporated in the model. The single-solute version of MADAM was able, however, to simulate/predict independent pilot data provided by the EPA about the adsorption of 1,2-dichloroethane in the presence of naturally occurring background organics in Ohio River water. (Brambley-SRC)
W82-00383

UPFLOW WATER FILTRATION UNIT, TEST RESULTS,
Oklahoma State Univ., Stillwater. Dept. of Agricultural Engineering.
C. E. Rice, M. L. Magnuson, and J. E. Garton.
Transactions of the ASAE, Vol 23, No 5, p 1143-1146, October/November, 1980. 5 Fig, 5 Tab, 5 Ref. OWRT-A-060-OKLA(2), 14-34-0001-6037.

Descriptors: *Water purification, *Filtration, Upflow filtration unit, *Rural areas, Turbidity, Domestic water, Farm ponds, Water supply, *Home-operated filter systems.

A rural homeowner-operated water filtration system for purifying surface waters and water from farm ponds was tested. Two different upflow-type water filtration and treatment units were compared. The large automatic unit (3 feet X 7 feet tank) included chemical feeder pumps and storage tanks for alum and chlorine, a pump and tank for pressurized-treated water, and liquid level controls. Filter medium was hydrous aluminum silicate. At a flow rate of 92 liters per min per square meter of filter area, this unit produced finished water at a rate of 16 gallons per minute with a turbidity of 2 NTU or less. This unit is large enough to supply the water needs of several households. The small unit (tank 1 x 1 x 5 feet) produced 414 gallons per day at a low rate of 1.15 gallons per minute for 15 minutes each hour. Alum concentrations were critical for proper results, frequent back flushing of the filter was required, and a water storage unit was necessary. Neither system clarified water with turbidity of 80 NTU or greater without pretreatment. (Cassar-FRC)
W82-00407

OZONE TREATMENT OF POTABLE WATER - PART I,
C. Nebel.
Public Works, Vol 112, No 6, p 86-90, June, 1981. 7 Fig, 4 Tab, 27 Ref.

Descriptors: Ozone, *Ozonation, *Water treatment, *Water purification, *Potable water, Domestic water, Drinking water, Taste, Odor control, Disinfection, Bacteria, Chlorination, Chemical treatment, Organic compounds, Heavy metals.

The use of ozone for treating drinking water is discussed. Ozone oxidizes organic pollutants and has the ability to act as a sterilant. It increases the characteristics of settleability, removal of organic compounds causing tastes, odors, and color, destruction of algae, and oxidation of iron, manganese, and heavy metals. The dosage level required for disinfection depends largely upon the amount of organic material present as well as the bacteria count. Heavy metals which can be controlled by ozone oxidations include lead, zinc, cadmium, and nickel. No solubility reductions can be expected for barium or calcium, since they have only one oxidation state. (Titus-FRC)
W82-00451

OZONE TREATMENT OF POTABLE WATER--PART 2,
C. Nebel.
Public Works, Vol 112, No 7, p 68-71, July, 1981. 5 Fig, 11 Ref.

Descriptors: *Ozone, *Organic compounds, *Disinfection, *Water treatment, Chlorinated hydrocarbons, *Trihalomethanes, Potable water, Ozonation, Chloroform, Coagulation, Humic acids, Activated carbon, Oxidation, Chlorination.

Part 2 of this paper discusses the role of ozone in oxidation of organic compounds and in the control of trihalomethanes (THM) in water treatment. Ozonation of dissolved organic materials yields polar and charged molecules which are more easily removed by alum coagulation. Those compounds readily oxidized include phenolics, detergents, pesticides, chemical manufacturing wastes, humic acids, polycyclic aromatic hydrocarbons, proteins, and amino acids. Formation of THM's in treated water may be controlled by ozonation. Of 80 water supplies surveyed, the only ones with no trace of THM's were produced by treatment facilities using ozone as a unit process. Although there are methods for preventing or removing THM's or their precursors, ozonation is less expensive and more effective than most of the others. Ozone may be added at the front of the plant to increase organics removal by alum flocculation, at the end of the treatment process for removing humic acids and other dissolved organics, or by combining ozone-activated carbon in the biological activated carbon process (BAC). Some of the BAC units have operated for six years without the need for reactivation. Ozone dosage levels are in the range of 1.5-4 mg per liter. Ozone as the only disinfectant can rarely be applied because the system to be treated must meet the following criteria: (1) dissolved organic content low enough to provide little food for bacteria, (2) low water temperature, (3) clean, high quality distribution system with low residence time, and (4) no ammonia. CHLORINATED DRINKING WATER,
C. A. Stewart, Jr.
Science, Vol 212, No 4499, p 1086-1087, June 5, 1981.

Descriptors: *Drinking water, *Chlorination, *Carcinogens, *Chloroform, Water treatment, Public health.

This letter to the editor discussed the suggestion that the presence of chloroform in drinking water may pose a public health risk. While it may be reasonable to conclude that chloroform might be a human carcinogen on the basis of test with rats and mice, it is not appropriate to conclude that chloroform is a human carcinogen. Occupational health standards indicate that exposures in the range of 0.1 to 10 grams per day pose a health risk. On the other hand, the exposure to chloroform from drinking water is 0.1 to 10 grams per lifetime. These data indicate that the number of excess cancers attributable to chloroform in drinking water is exceedingly small. The wide range of factors associated with the decision of to chlorinate water which have also been associated with cancer risk raises questions regarding any conclusion that increases in certain types of cancer are attributable to water chlorination. Finally, even if a clear association could be demonstrated, the question of whether the water was hazardous because it was chlorinated or chlorinated because it was hazardous would remain. WATER TREATMENT MODEL FOR POLLUTANT EXPOSURE ASSESSMENT,
Environmental Protection Agency, Athens, GA.
K. F. Hedden.
Journal of Environmental Science and Health, Part A, Vol 15, No 4, p 285-305, 1980. 2 Fig, 2 Tab, 20 Ref.

Descriptors: *Organic compounds, *Risks, *Assessments, *Model studies, *Water treatment, Activated carbon, Public health, Sedimentation, Coagulation, Flocculation, Filtration, Aeration, Chemical oxygen demand, Chemical wastes, Water pollution prevention, Effluents, Polyaromatic hydrocarbons, Carcinogens, Insecticides.

This paper describes a model of municipal water treatment processes for use in predicting the degree of removal of a toxic substance. Under the Toxic Substances Control Act, this information must be provided before new chemicals may be marketed. The subroutines include sedimentation, coagulation-flocculation (2 versions), filtration, aeration (2 versions), chemical oxidation, and granular activated carbon adsorption treatment. The chlorination model needs further experimental data and, in all probability, chemicals will need to be modeled on an individual basis. If the number and distribution of the population at risk and the necessary human and toxicological data are available, the potential health hazards of exposure to a chemical can be assigned. A sample run shows the removal rates for 11 selected chemicals: p-cresol, quinoline, methyl parathion, benzothiophene, 9H-carbazole, benzoquinoline, dibenzothiophene, 7H-dibenzocarbazole, benzoanthracene, benzopyrene, and mirex. 5G. Water Quality Control

QUARTERLY PROGRESS REPORT, NATIONWIDE URBAN RUNOFF PROGRAM.
Woodward-Clyde Consultants, San Francisco, CA.
Environmental Protection Agency Report, April 1980. 64 p, 3 Fig, 5 Tab, Append.

Descriptors: *Urban runoff, *Water quality control, *Water pollution control, Economic aspects, Pollutants, Water pollution treatment, Planning, Monitoring, Water use.

The progress and status of the Nationwide Urban Runoff Program for the first quarter of 1980 are summarized. Of the thirty prototype projects, ten are well underway and are yielding results, ten have approved work plans and adequate staffing, nine have submitted work plans which await approval, and one is still drafting a work plan scope. In fiscal year 1979 the projects spent a total of $6.22 million. Progress in each of the ten major tasks - program development, program management, 208 urban runoff status determination, agency program coordination, prototype project selection, work plan development, technical/management assistance, project monitoring/coordination, program assessment and evaluation, and nationwide assessment and report to Congress - is recorded. The appendix indicates the grantee, location, key staff, receiving waters, beneficial uses, suspected pollutants, impacts, candidate BMP's, budget, grant amount and status, project status, and problems, for each project. WQM FIVE YEAR STRATEGY (FY 81-BASELINE).
Environmental Protection Agency, Washington, DC. Water Planning Div.
Report, January 1980. 62 p, 2 Fig, 5 Tab, 20 Ref, 3 Append.

Descriptors: *Water quality management, *Long-term planning, *Legislation, *Management planning, Information systems, Nonpoint pollution sources, Monitoring, Water quality standards, Water treatment facilities, Runoff, Groundwater pollution, Financing.

The purpose of this strategy is to provide long-range direction for the water quality management (WQM) program to assist EPA Regions, States, areawide agencies, and the participating public with program planning in fiscal year 1981 and beyond, and to provide descriptions of program needs and directions. The focus is on WQM activities defined by sections 106, 208, and 303(e) of the Clean Water Act. The three highest management priorities for the program in FY 81-85 are improved program management, completion of the 208 grant program, and building and transferring an information base for nonpoint source control. Program priorities for the states include management of publicly-owned treatment works, monitoring, permits and enforcement, water quality standards, emergency responses, and nonpoint source management. The national 208 priorities are nonpoint source problems with the greatest emphasis on urban storm runoff, agriculture, and ground water contamination. Funding projections are made, based on historical data. The trend is to reduce federal funding with state and local agencies providing more funding. Four emerging policy issues are: coordination of 106 and 208 grants; water quality, quantity, and conservation; coordination of 201 and 208 programs; and coordination of WQM and other agency ground water activities. SELECTIVE OVERBURDEN PLACEMENT,
Bureau of Mines, Spokane, WA. Spokane Research Center.
G. G. Miller.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-135055, Price codes: A05 in paper copy, A01 in microfiche.
In: Surface Coal Mining Reclamation Equipment and Techniques, Proceedings: Bureau of Mines Technology Transfer Seminars, Evansville, IN, June 3, 1980, and Denver, CO, June 5, 1980. Bureau of Mines Information Circular 8823, 1980. p 54-59, 2.

Descriptors: *Water pollution control, *Ground water, *Coal mines, *Strip mines, Leaching, Trace metals, Mine wastes, Spoil disposal.

The current practice of identifying toxic ions of salts and trace metals at surface coal mining sites involves drilling on a 1 mile grid in unfaulted areas and on a 1/2 mile grid in faulted areas. Based on a study of a 100 acre premine site, a two-step drilling program is proposed. The overburden should be drilled on a 1/2 mile grid to identify which physiochemical parameters exist in inhibitory concentrations. Then the site should be drilled on a 100 to 200 foot grid to identify the extent of those parameters. It is desirable to suppress the leaching process in the presence of spoil containing inhibitory concentrations of trace metal or salts. This may be done in four ways: sealing with an impermeable layer; dilution through mixing; use of a topographic dome to divert surface water; and subsurface water can be consumed by plantlife. Clay capping was found to be effective as a barrier to saturated flow. Mixing of inhibitory spoil material with other clean spoil tends to dilute the concentration of inhibitory material to acceptable levels. A network of monitoring wells were placed in the overburden and spoil in a coal mine in Colstrip, southeastern Montana. Water levels and water quality measurements were taken. Data suggest that mining activities have had little effect on the overburden water levels at distances greater than 2,000 ft from the mine pit. No major changes in water quality have occurred owing to commercial mining at the site. (Moore-SRC)

METHOD AND APPARATUS FOR POLLUTANT SPILL CONTROL,
J. E. Turbeville.
U.S. Patent No. 4,234,420, 18 p, 7 Fig, 46 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1105, November 18, 1980.

Descriptors: *Patents, *Oil spills, *Oil pollution, Water pollution treatment, Water quality control, Adsorption, Equipment, *Water pollution control, Magnetic particles, Hydrocarbons.

Organic pollutant spills on aquatic bodies may be collected by a method comprising distributing buoyant magnetically susceptible, olephillic, hydrophobic, resilient sorbent particles on the surface of the pollutant, allowing the sorbent to attract and bind the pollutions, magnetically collecting the pollutant-bound surbent particles, compressing the pollutant-bound sorbent particles to expel the pollutant to a pollutant sump, allowing the compressed sorbent particles to recover from compression, and redistributing the sorbent particles on the surface of the remaining pollutant. An apparatus for the practice of the pollutant collecting method may be fabricated as a surface going aquatic vessel. (Sinha-OEIS)

MEANS AND METHOD FOR SWEEPING MATERIAL FLOATING ON WATER USING VIBRATIONAL ENERGY,
Ocean Ecology Ltd., Edmonton (Alberta). (Assignee).
J. N. Koblanski.
U.S. Patent No. 4,235,711, 6 p, 5 Fig, 3 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 4, p 1530, November 25, 1980.

Descriptors: *Patents, *Water quality control, *Water pollution treatment, *Oil pollution, *Oil spills, Acoustics, Sound waves, Vibrations, Equipment.

An apparatus for sweeping contaminating material such as oil along the surface of a body of water uses acoustic waves as a propelling force. The vibrational waves are produced by a device supported below the water surface and aimed upwardly towards a peripheral edge of the oil spill. Vibrational waves generated when the device is activated strike the air above the water surface and as a result are compacted into a flattened and horizontally elongated zone of vibrational energy which exerts a driving force on the oil spill edge. The method uses acoustical energy to provide, in effect, a huge broom which can be wielded to sweep floating oil or the like into a confined area from where it can more readily be picked up by other means. THE HORSE CREEK BASIN PROJECT,
Davis and Floyd Engineers, Inc., Greenwood, SC.
E. I. Davis, and W. J. Day.
Water/Engineering and Management, Vol 128, No 5, p 90, 92, 95, May, 1981. 2 Fig, 2 Tab.

Descriptors: *Wastewater facilities, *Regional planning, *Stream pollution, Pipelines, Industrial wastes, Natural streams, Water pollution sources, Water treatment, Horse Creek Basin, South Carolina.

Water treatment plans for the grossly polluted Horse Creek Basin and its major tributaries were designed to meet Environmental Protection Agency requirements. Construction and operation of a single regional plant which used an extended aeration-type wastewater treatment system was planned. Construction of the plant and the trunk system to collect the water to be treated began in 1977. The longest trunk line was 12 miles long, with the first three miles being a force main. One industry discharged alkaline waste into the stream, while another discharged a high pH waste. Unlined concrete pipe was used for the system. The project was completed in 1980 and the Horse Creek has already returned to a multiple-use waterway. The project has permitted development of a once blighted area. (Small-FRC)

ENVIRONMENTAL PLANNING FOR COAL STRIP MINING,
Loxton, Hunting and Associates, Gaberone (Botswana).
A. C. Venn, V. C. Barnes, N. Boegman, G. H. Grange, and J. F. V. Phillips.
Civil Engineer in South Africa, Vol 22, No 4, p 96-100, April, 1980. 1 Ref.

Descriptors: *Coal mining, *Water pollution control, Mining, Mine wastes, Acid mine drainage, Mine drainage, Acid streams, Planning, *South Africa.

Environmental planning and care of coal mining areas is viewed against the background that coal mining is a vital component of the national economy of South Africa. In general coal mining produces three water pollution problems: chemical pollution due to the well known pyrite oxidation reaction, which produces sulfuric acid and iron salts; washaways of coal slurry or coal fines which can produce serious suspended solids problems in

water, cause an oxygen demand, and lead to minor chemical pollution; and increases in the normal load of suspended solids which are more or less inert due to erosion of disturbed soil. The severity of these problems depends on locality with respect to rainfall surface water and underground water. Mining close to a river or stream creates specific problems in the prevention of pollution. The pyrite content of coal, the general slope of the workings, the method and direction of mining, and the method and degree of rehabilitation of the area attained after mining must also be considered. Current policies to attain a good degree of pollution control include the control of storm runoff, prompt removal of water from open-cast workings, arranging drains and sumps for rapid collection of groundwater, diversion of rivers, and control of seepage into and from open cast workings. Proper rehabilitation of the site is probably the most effective means of preventing water pollution from open-cast mining operations. (Baker-FRC)

GRAPHICAL EFFLUENT QUALITY CONTROL FOR COMPLIANCE MONITORING: WHAT IS A VIOLATION,
Illinois Environmental Protection Agency, Springfield.
D. J. Schaeffer, K. G. Janardan, H. W. Kerster, and M. S. Shekar.
Environmental Management, Vol 4, No 3, p 241-245, May, 1980. 1 Fig, 9 Ref.

Descriptors: *Sampling, *Effluent standards, *Regulations, Graphical methods, Monitoring, Water quality control, Water pollution control, Water sampling, Pollutant identification, Mathematical studies.

A graphical method is suggested to determine the mean value for compliance or non-compliance with pollutant discharge regulations. This avoids the problems of a too-narrow or too-wide allowable variation by eliminating 10% of the results from consideration. This proposed change would effectively double the allowable operating mean and the daily excursion point. Both regulators and dischargers would have a clear definition of satisfactory operation and multiple criteria (numerical compliance, expected variability, frequency, and magnitude of violations) for scoring compliance. Either composite or grab samples may be used. (Cassar-FRC)

Effluent and Water Treatment Journal, Vol 20, No 6, p 261-262, 265-266, 269, June, 1980. 2 Fig, 1 Tab, 7 Ref.

Descriptors: *Water pollution control, *Effluent standards, *Industrial wastes, Tidal rivers, Ecological effects, Water pollution effects, Stevenston, Scotland.

A case study of the development of consent conditions for a large ICI organics and explosives complex at Stevenston, Scotland, is presented. This facility discharges a variety of pollutants from manufacture of nitroglycerine, nitrocellulose, pentaerythritol tetranitrate, silicone oils, ammonium nitrate, lead styphnate, and dyestuff intermediates. The original design was to discharge all effluents 2 km at sea. However, the 12 million pound cost estimate caused a modification of the system. Two of 10 existing Garnock River outfalls and 2 short sea outfalls would be retained, with a long sea outfall to be constructed. Since effluent and storm water is combined, sensors will monitor overflows. A table lists the agreed limits for flow and other parameters. (Cassar-FRC)

ROCKY MOUNTAIN PIPELINE PROJECT: ENVIRONMENTAL IMPACT STATEMENT,
Bureau of Land Management, Washington, DC.
G. R. Konwinski, and W. N. Palmquist.
Available from the National Technical Information Service, Springfield, VA 22161 as DE81-026112, Price codes: A07 in paper copy, A01 in microfiche. Federal Energy Regulatory Commission, Office of Pipeline and Producer Regulation Report FERC/EIS-0024, TIC 92, July 1981. 59 p, 6 Fig, 3 Tab, 9 Ref, 1 Append.

Descriptors: *Environmental impact statement, *Environmental effects, *Construction, *Pipelines, Groundwater, Flood plains, Sediments, Stream pollution, *Water pollution prevention, Sediments, Intermittent streams, Streambeds, *Rocky Mountain Pipeline Project, Planning, *Erosion control, Sediment transport, Forecasting.

The Rocky Mountain Pipeline Project (RMPP) is a proposed 610-mile long natural gas transmission system. The RMPP would potentially cross many intermittent and perennial streams. The major concern with a pipeline stream crossing is the disruption of the streambed and the increase in sediment movement. The distance that the construction-induced sediment would be transported depends upon construction techniques, the stream flow parameters, and the grain size distribution of the stream bed materials. The disturbance of the streams cross section and the increase in sediment would be short term (3 to 5 days). It is expected that the levels of contaminants, such as lubricants and fuels introduced by construction into the waters that are crossed, will exceed state standards for short distances downstream, and mixing will be rapid. At some stream, road, and utility crossings and in some other topographically low areas, ground water may be encountered, but effects on groundwater would be localized and temporary. The proposed pipeline system would cross a floodplain at every stream crossing, but no aboveground permanent facilities would be constructed within a 100-year floodplain. Since regulations require that the pipeline be buried below the maximum scour depth, there would be no effects on flood stage. The pipeline will be hydrostatically tested in sections. The test water will be discharged in an environmentally acceptable manner. (Moore-SRC)

CONCEPTUAL DESIGN OF A REGIONAL WATER QUALITY SCREENING MODEL,
Argonne National Lab., Argonne, IL.
M. J. Davis.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/10151-T1, Price codes: A04 in paper copy, A01 in microfiche. Dept. of Energy Report DOE/EV/10154-T1, Jan, 1981. 57 p, 2 Fig, 7 Tab, 25 Ref, Append.

Descriptors: *Water quality, *Model studies, *Water pollution effects, *Model studies, Regional analysis, Environmental effects.

Various energy-related activities may result in water quality impacts of varying degrees of severity. There is a need for an improved capability to identify regions where negative impacts may occur. The purpose of this report is to present the background information and the conceptual basis needed for the design of a regional water quality screening model with such a capability. The model is intended for use in the Strategic Environmental Assessment System (SEAS) and also for use in assessments of water quality impacts in efforts such as the Regional Issue Identification and Assessment (RIIA) program. The proposed water quality model does not predict instream concentrations of pollutants for the present; measured concentrations are used to account for present conditions. The model does provide projections of future instream conditions based on some scenario for energy development and is intended for use in screening for potential problem areas. The model will allow existing flow and background concentration information for the Aggregated Sub-Area level to be used for studies at that scale. It will also allow smaller-scale studies to be done. The proposed model has a number of limitations: the neglect of localized effects having a spatial scale much smaller than that of the minimum spatial units used; the neglect of inputs from certain sources of water pollution; and the use of a simplified treatment of pollutant behavior. (Moore-SRC)

COMPUTER MODELING OF FLUID FLOW DURING PRODUCTION AND ENVIRONMENTAL RESTORATION PHASES OF IN SITU URANIUM LEACHING,
Bureau of Mines, Twin Cities, MN. Twin Cities Research Center.
R. D. Schmidt.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-160236, Price codes: A05 in paper copy, A01 in microfiche. Report of Investigations 8479, 1980. 72 p, 16 Fig, 1 Tab, 16 Ref, 4 Append.

Descriptors: *Computer models, *Leaching, *Groundwater movement, *Injection wells, Flow characteristics, Model studies, Groundwater pollution, *Uranium, Extraction, Pumping, Aquifers, Hydrologic models.

In situ leaching is one method that shows promise of being both economically and environmentally advantageous for extraction of uranium from low-grade ore deposits. This computer model is intended to describe the flow behavior of leachants and ground water during the development, production, and restoration phases of a leaching operation involving an arbitrary pattern of injection and recovery wells. The model enables an assessment of the effectiveness and acceptability of various well and pumping configurations, in terms of both fluid dispersion within the ore pod and fluid excursions into the surrounding aquifer. Different aquifer environments are modeled, using a closed-form solution to the partial differential equation that describes three-dimensional changes in piezometric head as a result of pumping from leachant injection and recovery wells. The computer program can model a maximum of 50 arbitrarily located wells. Numerical techniques involving difference quotients and Taylor expansions about time points are used to derive time, velocity, areal sweep, and fluid volume parameters associated with leaching hydraulics. These parameters are output by the program in graphic and tabular formats. (Moore-SRC)

Descriptors: *Coal, *Surface runoff, *Hydrologic models, *Water pollution prevention, Runoff models, *Runoff forecasting, Pollution load, Catchment areas, Water quality control, Precipitation, Infiltration, Erosion, Oxidation, Path of pollutants, *Coal pile runoff.

A model has been developed to aid in the prediction of the quantity and quality of coal pile runoff from utility sites. Quantitative data such as precipi-

tation, runoff/infiltration, percolation, snow-melt, and infiltration into ground water, are used in a hydrological model TRCH2O, and qualitative data such as pyrite oxidation, freeze/thaw of coal, gully erosion, and pollutant wash-off, are used in a qualitative model TRCCOAL. Output from TRCH2O combined with site specific data for TRCCOAL simulates the daily, monthly, and annual run-off flows and loadings of pollutants such as acid, iron, sulfate, and trace metals. A field program for model validation will be conducted. Once validated the model can be used in the design of runoff collection basins and treatment systems, with the object of achieving site-specific designs, rather than the current arbitrary designs. (Brambley-SRC)

WATER POLLUTION POTENTIAL OF COAL-SLURRY PIPELINES,
Montana State Univ., Bozeman, Dept. of Civil Engineering and Engineering Mechanics.
H. S. Peavy.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-187221, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-082, June 1981. 6 p, 2 Fig, 6 Tab.

Descriptors: *Coal, *Slurries, *Pipelines, *water pollution sources, *Chemical reactions, Hydrogen ion concentration, Minerals, Dissolved solids, Turbidity, Organic carbon, Alkalinity, Colloids, Planning.

Coal-slurry pipelines have been proposed as one economical means of transporting coal over long distances to specific markets. The objective of this research project was to characterize those contaminants associated with transport waters from coal-slurry pipelines. This was accomplished through tests using a rotating bench-scale reactor. Tests consisted of coal mixed with tap water, tap water with additives, synthetic saline water, and synthetic saline water with additives. Tests were performed for a period of 12 days each. The results indicate that chemical interactions do occur between water and coal-slurry pipelines. There was a decrease in pH of approximately two units (from approximately 8 to approximately 6). Dissolution of metals at a pH of 6 was not significant. An increase in mineral content of fresh water was observed. Alkalinity, total dissolved solids (as indicated by electrical conductivity), and sulfates each showed increases. Use of phosphorus-based chemical additives for corrosion control resulted in substantial concentrations of phosphate. Turbidity remained in the water after separation of the coal by centrifugation. Although some color may be present as a result of humic acids and manganese, colloidal particles appeared to be the main cause of turbidity. Dissolved organic carbon levels may be significant if reuse (either prior to or after discharge) requires chlorination. These organics are potential percursors of chlorinated hydrocarbons. WATER, ENERGY AND LABOR REQUIREMENTS FOR FUTURE PACIFIC NORTHWEST IRRIGATION,
Oregon State Univ., Corvallis. Dept. of Agricultural Engineering.
L. D. King, and M. L. Hellickson.
Transactions of the ASAE, Vol 24, No 3, p 691-698, May/June, 1981. 8 Fig, 1 Tab, 14 Ref.

Descriptors: *Irrigation, *Planning, *Computers, Model studies, Costs, Economic aspects, Agriculture, *Pacific Northwest, Energy, Labor.

A computer model was developed to determine future water, energy and labor requirements for three projected levels of irrigation development. Irrigation systems were selected by minimizing irrigation costs by crop for each of 45 hydrologic basins in the region. Results indicate that per acre energy requirements will increase rapidly as per acre water and labor requirements decrease. The study area was located in the Pacific Northwest. Data collected included levels of irrigation development, water, energy, labor cost and trends, and capital investment of irrigation systems; irrigation system labor requirements, expected useful system life, and estimated changes in irrigation efficiency. Pump-back and similar technologies at present offer the possibility of both increasing application efficiency and conserving energy. However, they have the disadvantage of a high labor requirement. The relationships between applying water in quantities greater than required for crop consumption and late season in-stream flow augmentation and/or aquifer recharge are not well understood. However, they should be investigated before major changes are made in regional water-energy management schemes. (Baker-FRC)

THE LIMITATIONS AND USEFULNESS OF STREAMFLOW GENERATION METHODS: A CASE STUDY,
Saskatchewan Univ., Saskatoon. Dept. of Civil Engineering.
W. J. Stolte.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 185-191, 1980. 2 Fig, 3 Tab, 9 Ref.

Descriptors: *Reservoir design, *Streamflow forecasting, *Probabilistic process, Design criteria, Dams, Red Deer River, *Alberta, Model studies, Stochastic process, Hydrology, Statistical analysis, Case studies.

The increasing complexities of probabilistic models have made the connections between models and the physical world more and more vague. As a result, engineering judgement tends to be deemphasized. The models' validity is assumed even when practical verification must await future events. Results of generated streamflow sequences for the dam and reservoir being constructed on the Red Deer River, Alberta were compared with 61 years of recorded data. Both a simple autoregressive model and a more complex autoregressive moving average model had similar deficiencies. The generated and recorded peak monthly flows and minimum flows were comparable, but the generated sequences reached minimum levels faster than did actual flows. The value of stochastic streamflow generation lies in predicting reservoir storage failure. However, it is not so reliable as recorded data as a basis for hydrologic design of reservoirs. BASIN MANAGEMENT IN THE SAN BERNARDINO BASIN AREA,
San Bernardino Valley Municipal Water District, CA.
L. W. Rowe.
Ground Water, Vol 18, No 6, p 626-629, November-December, 1980.

Descriptors: *Management planning, *Drainage basins, *Computer applications, Hydrologic data, Monitoring, Project planning, Economic aspects, Data interpretation, Rainfall, Watersheds, Groundwater, Water supply, Pumps, *San Bernardino Valley, California, *Watershed management.

The San Bernardino Valley Municipal Water District was formed in 1954 to master plan the long-term water supply, including the importation of supplemental water for a portion of the Upper Santa Ana River Basin. As part of its function, the District has established a hydrologic data base. Development and selection of the alternative strategies is more effective with historic and real time hydrologic data. The updating of the operation economics associated with importation also benefits from availability of hydrologic data. Water quality data is obtained through an ongoing monitoring program. Eight service areas within the District investigate the feasibility of introducing supplemental water, either through groundwater recharge or direct filtration, to augment native supplies. Groundwater models are used in the development of management practices. The Cooperative Water Project is an arrangement between public and private water purveyors which provides a system for exchanging water credits during periods of short supply. The District also identifies excess pumpage and wheeling capacity within existing water systems, and engages in regional public participation programs. (Titus-FRC)

Louisiana State Univ., Baton Rouge. Dept. of Civil Engineering.
M. L. Tittlebaum, J. L. Pavoni, B. F. Maloy, and T. L. Kochert.
Public Works, Vol 111, No 1, p 40-41, January, 1980. 1 Fig, 6 Ref.

Descriptors: *Disinfection, *Chlorination, *Decision making, Planning, Wastewater treatment, Residual chlorine, Aquatic life, Public health, Toxicity, Chlorinated hydrocarbons, Environmental effects, Water quality.

A decision-making tree for choosing wastewater disinfection alternatives is described. High priority is given to water quality and environmental effects, in particular, eliminating hazards from pathogens and halogenated organic compounds and protecting aquatic life from residual chlorine toxicity. Possible disinfection methods include chlorine, chlorine dioxide, ozone, ultraviolet radiation, bromine chloride, and dechlorination. However, most of the disinfectants currently being considered for wastewater treatment have serious limitations, so potential applications must be considered on a case-by-case basis. (Cassar-FRC)

Descriptors: *Rural areas, *Water distribution, *Water treatment facilities, Water demand, Water treatment, Water supply systems, Water conveyance, Pipelines, Water mains, Water use, Water shortage, Farms, *Madison County, Illinois.

A successful rural water district plan was developed in Madison County, Illinois with the aid of Farmers Home Administration (FmHA) funding. The design of the total water system, which would provide water to drought-stricken farms previously supplied by wells, included 78 miles of water main, an elevated and a ground storage tank, two booster pump stations, telemetry and appurtenances. The project was built to handle 550 users with a 35% growth factor. The city of Edwardsville contracted to supply one million gallons of water per month to the Northeast Central County Public Water District (NCCPWD) in turn for monies to help upgrade their current treatment facility. The operations of the new NCCPWD system are diagrammed, and special provisions for large family dwellings and pipeline safety when laid beneath roadways are discussed. Early installation of house services allowed the district to receive revenue from the project six months prior to its completion in July of 1980. The director of the FmHA attributes the success of this water district project to the accurate assessment of water demand, the capability and flexibility of the contractor, the close communication between the Board of Trustees and residents, and the project's

innate designs to easily accommodate expansion. Total cost of the project was about $3 million, of which a little less than $1.4 million was borrowed. (Geiger-FRC)

Descriptors: Water resources, *Climatology, Planning, *Weather, *World Meteorological Organization, World Climate Program, Decision making, Water policy, International commissions.

The World Meteorological Organization established the World Climate Program in May 1979 as an international effort to foresee climatic changes and to use this knowledge in planning and management of man's activities. The Climate Study Program, one of the four components of the overall program, will concern formulation of rational policy alternatives in agriculture, water resources, ocean resources, fisheries, land use, etc. The Program will be operating on time scales from several weeks to several decades and on space scales from regional (1000 km) to global. ANALYSIS OF CAPACITY REQUIREMENTS FOR STORAGE RESERVOIRS: A CASE STUDY,
Calgary Univ. (Alberta). Dept. of Civil Engineering.
I. Musik.
Canadian Journal of Civil Engineering, Vol 7, No 2, p 388-392, 1980. 3 Fig, 2 Tab, 8 Ref.

Descriptors: *Reservoir storage, *Storage requirements, *Stochastic process, Red Deer River, *Alberta, Streamflow, Drought, Case studies.

Three procedures for estimating reservoir storage from 61 years of historic mean monthly flows on the Red Deer River, Alberta, were considered. The stochastic simulation approach proved best because it allowed full extraction of information from the historic data on properties of inflow and generated 99 series of 100-year mean monthly flows for storage requirements analysis. The method of computing required storage capacity from the historic sample produced the minimum storage capacity, 225 million cu meters, but could not assign any probability of failure to satisfy the required yield. Using synthetic mass curves produced unrealistically high storage values because the curves did not indicate a realistic sequence of natural flows. (Cassar-FRC)

Descriptors: *Soil water, *Surface water, *Flow discharge, *Salts, *Flow pattern, Soil physical properties, Simulation analysis, Drainage, Irrigation practices, Diffusion coefficient, Flow velocity, Unsaturated zone, Prediction.

This investigation was undertaken to develop procedures for evaluating distribution of water and salt fluxes over land areas. Relevant applications include numerical simulations and sampling in fields of large extent. The primary focus is on irrigated lands including effects of salinization and crops on the ground and surface waters. The study was in three parts: observations of distributions for a variety of soil physical parameters and inference on sampling; simulations of water and salt fluxes for nondeterministic systems; and a sensitivity analysis for drainage. Simulations of water and salt fluxes were made using the 'crude' Monte Carlo technique. For infiltration, 'Philip's' equation was utilized in a scaled form by solving one time. Individual simulations were made algebraically without repeating the laborious steps of resolving the unsaturated moisture flow equation each time. Similarly, results for the nonlinear drainage case were solved based on only one finite difference determination. The Monte Carlo simulation was carried out by simple interpolation from the one nonlinear solution. Unfortunately, no great shortcut was found for cyclic or seasonal irrigation regimes, although some interesting results based on linearized solutions were found for high frequency water applications. Salt distributions were calculated for cases of equal irrigation amounts over time but with intake rate varying over space. Deterministic calculations based on the mean velocity and apparent diffusion coefficient gave erroneous results compared to the 'average' values over the field for both salt profiles or fluxes. The true 'average' by depth for a given time is much more dispersed, with more salts reaching very deep depths and also with more salts remaining close to the surface when pulses of salt are added. Similarly, the mass emission of salts averaged over a field for a given depth appear earlier in time and taper off more gradually for a pulse input than deterministic calculations based on mean velocities would indicate. ALTERNATIVES WORKING GROUP REPORT.
Available from the National Technical Information Service, Springfield, VA 22161 as CONF-800137, Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U.S. Dept. of Energy's National Workshop, Jan 29-31, 1980, Albuquerque, NM. Dept. of Energy Report CONF-800137, Nov 1980. p 167-183, 3 Fig, 1 Ref.

Descriptors: *Groundwater potential, *Groundwater availability, *Water supply development, *Legislation, Federal jurisdiction, State jurisdiction, Water rights, Environmental effects, Economic aspects, Social aspects, Water conservation, Impaired water use.

The working group discussed various technical and institutional alternatives for ground water use in energy development. As energy activities compete with other users for water supplies, ground water will become an attractive option. A matrix was developed to identify the attributes of ground water problems. Surface and ground water supplies are considered in relation to their physical availability; reliability; the impact of state laws, purchase rights and Federal laws on the water rights; environmental effects on water, air, and land; cost; and social acceptance. Using the matrix a small number of possible sources can be identified. Further consideration in light of cost and social acceptance should reveal the best water source. This analysis should take into consideration process changes such as dry cooling, recycling, and reuse; use of process-derived water; and technological substitution; all of which reduce the water demand or make use of low quality water. M. J. Davis, and S. Chiu.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/10154-01, Price codes: A04 in paper copy, A01 in microfiche. Dept. of Energy Report DOE/EV/10154-01, Nov, 1980. 64 p, 7 Tab, 67 Ref, 2 Append.

Descriptors: *Water quality, *Environmental effects, *Water pollution effects, *Fuel, Waste disposal, Resources development, Groundwater, Regional analysis, Energy sources.

A number of water quality issues will arise during assessments of the environmental impacts associated with various energy futures. Realistic assessment of the water quality impacts associated with future energy development requires that the most significant of these issues be properly addressed. The purpose of this report is twofold: first, to identify and to evaluate significant water quality issues related to regional and national assessments of energy developments; and second, to recommend for study related topics that bear on the capability to carry out such regional and national assessments. Issues concerning impacts on water quality include: impact of secondary effects of energy development; spills and accidental releases of pollutants; noncompliance with discharge requirements; solid waste disposal; coal mining; consumptive use and the maintenance of instream flow requirements; impacts on groundwater quality due to leaching, aquifer disruption, saltwater intrusion, waste disposal, and depletion; importance of hydroelectric load following for downstream conditions; inputs of pollutants to the Great lakes; atmospheric deposition and acid rain; salinity and energy-related residuals in the Colorado River Basin; biomass residue harvesting; synfuel development; and water quality impacts of energy developments in the coastal zone. Methodology issues in surface water quality assessments include: load estimation techniques; proper description of river basins; and water quality modeling procedures. (Moore-SRC)

REPORT OF SURVEY OF CORPS OF ENGINEERS CONSTRUCTION WORKFORCE,
Institute for Water Resources (Army), Fort Belvoir, VA.
C. M. Dunning.
Available from the National Technical Information Service, Springfield, VA 22161 as AD-A103324, Price codes: A07 in paper copy, A01 in microfiche. Research Report 81-R05, June 1981. 135 p, 3 Fig, 41 Tab, 31 Ref, 3 Append.

Descriptors: *Employment, *Social aspects, *Construction, *Economic impact, Benefits, Cost-benefit analysis, Dam construction, Unemployment, Reservoir construction, Flood control, *Engineering personnel, *Corps of Engineers.

A survey of the Corps of Engineers construction workforce was conducted in order to develop an

empirical basis for determining employment benefits due to construction of Corps projects, and to develop an empirical basis for determining the socioeconomic impacts of the workforce utilized for Corps project construction on local communities. The study is based on a 51-project sample selected from 136 projects constructed during 1979. The data base represents 4,089 complete responses from workers at a cross-section of Corps projects. Project types include: flood control, reservoirs, power projects, channels and harbors, locks and dam projects, beach erosion projects, and replacement projects. Some unemployment immediately prior to beginning work on Corps projects was reported by 39.6% of the workers. Clear differences in previous unemployment status were found among the workforce according to occupational group, locality, and the project area EDA status. The survey revealed that a large majority of the Corps' construction workforce is composed of local workers (69.4%). Approximately 60% of the non-local workforce is accompanied by dependents. A ratio of 1.24 dependents to each non-local worker was computed. For non-local workers, nearness to project site seems to be the most important housing choice location criterion. (Moore-SRC)

OPTIMAL DESIGN OF WATER CONVEYANCE SYSTEMS,
Texas Dept. of Water Resources, Austin.
Q. W. Martin.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 106, No HY9, p 1415-1433, September, 1980. 5 Fig, 2 Tab, 15 Ref.

Descriptors: *Water conveyance, *Design criteria, Conveyance structures, Water distribution, Aqueducts, Computers, *Cost analysis, Water supply systems, *Texas.

A procedure is described for establishing the minimum cost design and location of a water conveyance system. The design problem considered is limited to the evaluation of the construction of conveyance facilities to their ultimate flow capacity without consideration of capacity expansion. The application of the method is described for a potential water conveyance canal from Lake Texoma on the Texas-Oklahoma border to the upper Trinity River Basin watershed. The various corridors for a potential water conveyance facility from Lake Texoma to the Basin were evaluated using the largest scale US Geological Survey topographic map available. The use of the demographic and topographic information led to the immediate elimination of certain portions of the potential route. Some of the territory was occupied by cities or wildlife refuge locations, or was of high elevation. The remaining area was then examined using topographic maps based on a smaller scale. Using a composite map of four, 15 minute quadrant sheets, a set of 110 possible conveyance route sections and 90 junction points between the sections was delineated. The CANAL-I program is able to analyze up to 174 junctions and 250 route sections, with additional junction points and route sections being added to provide further detail. Several computer runs using CANAL-I were required. The use of this program significantly reduced the time required to determine reconnaissance level design for the water conveyance system. It is expected that in the future, use of this program will significantly cut costs in the construction and operation of water conveyance facilities. (Baker-FRC)

WORTHLESS, VALUABLE, OR WHAT. AN APPRAISAL OF WETLANDS,
Vermont Univ., Burlington.
J. Brande.
Journal of Soil and Water Conservation, Vol 35, No 1, p 12-16, January/February, 1980. 23 Ref.

Descriptors: *Wetlands, *Economic aspects, *Attitudes, Marshes, Swamps, Value, Drainage effects, Ecological effects, Hydrologic cycle, Hydrological regime, Reviews.

Wetlands have been recognized as having a positive value only in the past 30 years. This paper traces history of the negative attitude toward wetlands, swamps, and marshes from Hippocrates in the fourth century B.C., through Roman times, Shakespeare's writings, early American colonial leaders, and surveyors of the Dismal Swamp in Virginia to the recent literature. It is now realized that wetlands can improve water quality, store floodwaters, recharge groundwater supplies, provide habitat for wildlife and an environmental margin of safety, produce useful materials (peat, fish, game), protect shorelines from erosion, provide recreational and educational opportunities, purify the air, act as sound barriers, and provide a genetic reservoir. The vast amount of data on wetlands now being acquired must be translated and interpreted so that society can understand and use it, especially the economic aspects. If monetary values for the variety of wetland functions are assigned, the true value of these formerly 'dangerous' and 'worthless' areas may be realized. (Cassar-FRC)

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: LEWIS RIVER BASIN, WASHINGTON.
Federal Energy Regulatory Commission, San Francisco, CA. Office of Electric Power Regulation.
Report FERC-0067, January 1981. 59 p, 13 Fig, 6 Tab.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *Flood control, Economic feasibility, Irrigation, Water supply, Navigation, Recreation, Water quality, Groundwater availability, Appraisals, *Lewis River basin, Washington.

The Lewis River basin has an area of 1,046 sq miles and there are four hydroelectric projects on the river. All but one are storage projects, which provide significant seasonal flow regulation of the river. The water resources of the basin have also been developed for irrigation, flood control, water supply, navigation, and water-based recreation. The license for the Merwin project has expired and it is being considered for relicensing. The plant is in good condition and the project appears to be economically favorable for continued operation. The major water resource management problems in the basin are related to water quality, groundwater availability, and municipal water supply, with flooding, preservation of instream flow values, and undeveloped water-related recreational potentials as lesser considerations. Seventeen conventional hydropower sites have been identified, but the economic feasibility of each project has not been determined. (Brambley-SRC)
W82-00370

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: ELWHA RIVER BASIN, WASHINGTON.
Federal Energy Regulatory Commission, San Francisco. Office of Electric Power Regulation. Report FERC-0072, March 1981. 46 p, 11 Fig, 7 Tab, 6 Ref.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *National parks, Water supply, Flood control, Recreation, Economic feasibility, Project planning, Fish management, Appraisals, *Elwha River basin, Washington.

The Elwha River basin has an area of about 321 sq miles, most of which is within national park or national forest boundaries. The water resources of the basin have been developed to provide for water supply, flood control, recreation, and hydropower. There are two hydroelectric plants on the river, and, given the restrictions on development within national parks, it is unlikely that further development will be allowed. The Glines Canyon Dam is within Olympic National Park, and functions essentially as a run-of-river powerplant. It is well maintained and seems to be an economical source of power and recreational activities for many years. Five potential conventional and hydroelectric and one potential pumped storage site have been considered, but will not now be developed. At both projects regulation for minor flood control should be undertaken. It is recommended that a fish passage facility be constructed at the Elwha Dam, and that Lake Aldwell be regulated in the future to provide water supply and streamflow regulation for fish. (Brambley-SRC)
W82-00371

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: LITTLE TENNESSEE RIVER BASIN, TENNESSEE, NORTH CAROLINA, AND GEORGIA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation. Available from Supt. of Documents, GPO, Washington, DC 20402. Report FERC-0066, January 1981. 83 p, 17 Fig, 19 Tab.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *Economic feasibility, Project planning, Water level fluctuations, Minimum flow, Environmental effects, Fish management, *Little Tennessee River basin, Tennessee, North Carolina, Georgia.

The Little Tennessee River basin has an area of 2,627 sq miles; the river is 602 miles long, and there are 17 licensed hydroelectric developments in the basin. Six other projects have license applications pending. Together they have an installed capacity of 93,975 kilowatts. All the projects are in good physical condition and appear to be capable of providing an economic source of power for the foreseeable future, and it may be economic to expand them. Minimum flow regulations and reservoir water level fluctuations for the benefit of fish are considerations in the possible licensing of these projects. The projects are economically justified, and are not environmentally harmful. There is potential for further hydroelectric development in the basin, up to 4,000 megawatts, 98% of which would be from pumped storage. (Brambley-SRC)
W82-00372

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: PIT RIVER BASIN, CALIFORNIA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation. Available from Supt. of Documents, GPO, Washington, DC 20402. Report FERC-0045-2, September 1980, 85 p, 39 Fig, 22 Tab, 8 Ref, Append.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *Economic feasibility, *Flood control, Environmental effects, Fish management, Dam construction, Irrigation, Recreation, Land use, Appraisals, *Pit River basin, California.

The Pit River basin has an area of 6,100 sq miles, and there are nine hydroelectric developments on the Pit River with a generating capacity of 725,150 kilowatts. The license for Project 233, comprising three developments, has expired, and the project is

being considered for a new license. The plants are in good operating condition and can continue to be an economic source of power. Continuation of the existing reservoirs would not have significant adverse effects on the environmental aspects of the basin, but some alterations in operation may be necessary to improve fish management. Flood control is needed in the basin to alleviate flooding downstream on the Sacramento River. Since it would not be economic to use or modify the existing hydroelectric projects for this purpose, new projects have been suggested. The Allen Camp project would provide benefits from irrigation, recreation, flood control, power, fish and wildlife enhancement, and area development, and would possibly provide headwater improvement to hydroelectric power at the downstream plants, but since the original study this project has become unfavorable economically. One of the three potential hydroelectric projects is considered economically favorable. (Brambley-SRC)
W82-00373

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: CLARK FORK-PEND OREILLE RIVER BASIN, MONTANA, IDAHO, WASHINGTON.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation.
Available from Supt. of Documents, GPO, Washington, DC 20402. Report FERC-0062, September 1980. 108 p, 37 Fig, 32 Tab, 8 Ref.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *Economic feasibility, Project planning, Water conservation, Irrigation, Municipal water, Flood control, Water quality control, Recreation, Wildlife management, Colorado River basin, *Clark Fork-Pend Oreille River basin.

The Clark Fork-Pend Oreille River basin is a major component of the Columbia River basin, having a drainage area of 25,800 sq miles, of which 1,203 sq miles are in Canada. There are 13 hydroelectric generating plants in the United States portion. The license for the Thompson Falls plant expired in December 1975 and was renewed in December 1979, and the license for the Kerr plant expired in May 1980 and is currently operating under an annual license. This plant is in good physical condition and is capable of providing an economical source of power for an extended period. Preliminary studies indicate that an additional generating unit would be economic. Thirteen potential conventional power projects and five additions to existing hydroelectric projects are discussed. The principal purposes of these developments would be to provide hydroelectric power, water conservation for irrigation and municipal supply, and flood control, with consideration being given to fish and wildlife management, water quality control, and water-oriented recreation. A preliminary economic analysis of the new projects indicates that five projects have favorable energy economics, while four of the five additions are economically favorable. (Brambley-SRC)

THE VALUATION OF RECREATIONAL FISHERIES,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
D. Cauvin.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 8, p 1321-1327, August, 1980. 17 Ref.

Descriptors: *Recreation demand, *Fisheries, *Resources allocation, Value, Pricing, Economic aspects, Resources allocation, *Canada.

The present concept of recreational fisheries in Canada as a nonpriced resource should be changed. These techniques do not allow a realistic value to be assigned for allocation and management decision making. Two valuation techniques, favorable in Western Canada, are discussed--the willingness to pay method and the expenditure method. When the government provides free or nominal-cost fishing, overallocation of resources for fisheries or distorted demand statistics result. The argument is made that recreational fishing should be priced in spite of the difficulties and of the opposition posed by fishermen and by governmental agencies charged with administration of this work. 6D. Water Demand

GROUND WATER AVAILABILITY,
Geological Survey, Denver, CO. Water Resources Div.
H. H. Hudson.
Available from the National Technical Information Service, Springfield, VA 22161 as CONF-800137. Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U. S. Department of Energy's National Workshop, January 29-31, 1980, Albuquerque, New Mexico. Department of Energy Report CONF-800137, November 1980. p 37-47, 13 Ref.

Descriptors: *Groundwater availability, Groundwater potential, *Resources development, *Water supply, Surface water availability, *Water demand, Oil shale, Coal, Energy sources, Regional development.

When water requirements for energy resource development are considered, it is generally only surface water that is considered. In both the Upper Missouri and Upper Colorado River basins there are extensive coal and oil shale reserves, but the surface water reserves which are not already allocated are inadequate. In studies in which scenarios were developed, water sources were generally not indicated. The more recent studies indicate that less water would be needed than the earlier studies indicated. While surface water resources are well known, ground water resources tend to be estimates, with quantity and quality unknown. It is suggested that this ground water resource may provide the water necessary for energy development, once the supply is sufficiently studied. Water of low quality, which is unsuitable for domestic or agricultural purposes, may be suitable for energy development processes, particularly in coal-slurry pipelines. Use of ground water may overcome some of the legal, economic, political, institutional and environmental conflicts which accompany the use of surface water. (Brambley-SRC)

GROUND WATER ALTERNATIVES AND SOLUTIONS,
Los Alamos Scientific Lab., NM.
F. Roach.
Available from the National Technical Information Service, Springfield, VA 22161 as CONF-800137, Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U.S. Department of Energy's National Workshop, January 29-31, 1980, Albuquerque, New Mexico. Department of Energy Report CONF-800137, November 1980. p 65-94, 13 Fig.

Descriptors: *Water supply, *Water demand, *Economics, *Groundwater potential, Groundwater availability, Groundwater depletion, Resources development, Aquifers, Saline water, Surface water availability, Energy sources, *Impaired water use.

It is generally acknowledged that surface water supplies will not be able to meet the demands of a developed energy industry in many areas of the U.S. Increasing claims on this resource may put the price out of an economic range for energy or other users. Using maps of energy resources, surface water, ground water use, and saline and deep aquifers, it can be shown that while the energy resources generally occur in areas with surface water problems, they occur outside areas with high ground water use. They coincide well with areas of saline and deep aquifers. Saline and low quality water has applications in the energy industry such as: in cooling water systems; air pollution control systems; waste disposal; conversion process modifications; mining; and coal slurry pipelines. Use of saline water has the economic advantages of lower development costs, adding little to the product price, and lessening the political and transaction costs. The use of ground water, and ground water in conjuction with surface water, is a solution to the water needs of the energy industry, and there are opportunities for the industry to cooperate with other users in developing water sources for all. (Brambley-SRC)

SUPPLY WORKING GROUP REPORT.
Available from the National Technical Information Service, Springfield, VA as CONF-800137, Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U.S. Department of Energy's National Workshop, January 29-31, 1980, Albuquerque, New Mexico. Department of Energy Report CONF-800137, November 1980. p 131-144, 2 Ref.

Descriptors: Groundwater availability, *Groundwater potential, *Geohydrology, *Hydrologic cycle, Water supply, *Water demand, Surface water, Energy sources.

The primary objective of the Supply Working Group was to discuss the Office of Technology Impacts' (OTI) procedures for assessing the potential impacts of using ground water for energy production. Four levels or categories of OTI assessments were thought to be necessary: national, State/regional, basin, and site-specific. The needs of the national assessment could be met by collecting and summarizing information on ground water across the nation, but the other three levels of assessment would require more than an aggregation of available information. Ground water is part of the hydrologic cycle and cannot be considered separately from surface water when water supplies are being assessed. At the basin or aquifer level, an interpretation of the hydrologic unit requires the following information: geologic configuration, aquifer and basin boundaries, recharge and discharge, capture potential, storage capabilities, transmissive qualities, quality characteristics, transport or dispersive qualities, water dating, and water demand. Development of ground water is possible only when it is hydrologically and economically feasible and will always be accompanied by declining water levels and stream flow depletion. The group identified data base issues, fundamental issues, saline aquifer issues, impacts of ground water development, permit and legislation issues, modeling, relocation and reallocation, and general issues. WATER RELATED PLANNING AND DESIGN AT ENERGY FIRMS,
Los Alamos Scientific Lab., NM.
D. Abbey, and F. Lucero.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/EV/10180-1, Price codes: A03 in paper copy, A01 in microfiche. Department of Energy Report DOE/EV/10180-1, November 1980. 44 p, 8 Fig, 6 Tab, 23 Ref.

Descriptors: *Water demand, *Water allocation, *Planning, *Powerplants, Cost analysis, Water use, Cooling water, Water scarcity, Wastewater treatment, Waste disposal, Water treatment, Water reuse, Energy sources.

Energy production and conversion activities have historically been water intensive, so accelerated domestic energy production is expected to make increased demands on water resources. By identifying production alternatives and specifying their costs under a variety of conditions, future patterns of water use in the energy industry and its response to water-related regulation may be projected. The three principal decisions of industry that affect water allocation are where to build plants, where to get water, and how much water to use. Site selection is currently based on water supplies for evaporative cooling; this may change in response to increasing water scarcity. Water may be acquired from a number of sources; the source will be selected on the basis of uncertainty, risk, transaction and engineering costs. Water system design entails the evaluation of tradeoffs among water intake, water treatment, and wastewater disposal costs. A survey of recently constructed and planned plants shows that water supply costs are site-specific, and the following conclusions may be drawn. If water intake or disposal costs are nonzero, recirculating systems are cheaper than once-through systems. Treatment costs for low quality water may be less than transport costs for high quality water. Discharge standards and disposal costs promote the maximum degree of recirculation, reuse, and treatment. Dry cooling has great potential for application at synthetic fuel plants and very limited potential at electric plants. (Brambley-SRC)

Environmental factors are frequently omitted from energy supply models. This report describes a tool for water and energy related policy analysis, the development of a water supply and demand sector in a linear programming model of energy supply in the United States. The model allows adjustments in the input mix and plant siting in response to water scarcity. On the demand side, energy conversion facilities can substitute more costly dry cooling systems for conventional evaporative systems. On the supply side, groundwater and water purchased from irrigators are available as more costly alternatives to unappropriated surface water. The availability of water was determined from water basin information for 30 regions in 10 Western states. Preliminary results for a 1990 energy demand scenario suggest that, at this level of spatial analysis, water availability plays a minor role in plant siting. Certainly, there are legal and institutional impediments to the procurement of large industrial water supplies. But, as represented by the structure and data inputs of the model, there are a variety of water use alternatives available to energy firms when any one option is foreclosed. (Moore-SRC)

A 10-YEAR PLAN TO STUDY THE AQUIFER SYSTEM OF INDIAN WELLS VALLEY, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
P. Lipinski, and D. D. Knochenmus.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $5.75 in paper copy, $5.00 in microfiche. Geological Survey Open-File Report 81-404, June 1981. 16 p, 4 Fig, 12 Ref.

Descriptors: *Planning, *Aquifer systems, *Groundwater, *Water resources development, Pumpage, Over-draft, Groundwater recharge, Observation wells, Water level, Water quality, Model studies, Prediction, Evaluation, Water management, *California, Indian Wells Valley, China Lake.

Water needs of the population of Indian Wells Valley, Calif., must be met through further development of ground-water resources. Studies show that annual ground-water pumpage there has increased since 1945 and has exceeded mean annual recharge since 1966. Continued and increased stress on the aquifer system of the valley is expected because population in the valley is predicted to double by 1998 and triple by 2020, based on 1977 population figures. The U.S. Geological Survey proposes a 10-year program to develop a data base to aid in evaluation of future water-management alternatives. A study plan has been developed that describes present and potential problems and objectives of the program, and outlines work items to be undertaken in the study area. (USGS)

WESTERN WATER RESOURCES: COMING PROBLEMS AND POLICY ALTERNATIVES,
Federal Reserve Bank of Kansas City, MO.
M. Duncan, and A. Laing.
Journal of Soil and Water Conservation, Vol 35, No 3, p 192-195, July/August, 1980. 2 Fig.

Descriptors: *Water policy, *Water law, *Water allocation, *Water management, Water resources development, Water demand, Water supply, Water shortage, Water conservation, Western states, Legislation, Decision making, Financing, Legal aspects, Political aspects, Economic aspects.

Water resources in the western United States are becoming increasingly scarce and expensive. A symposium in Denver, Colorado, examined the coming problems and some policies for coping with them. The two fundamental difficulties in formulating a natural resource policy are finding the right balance between private and public resource development, and the harmonization between individual and group decision making. An area of great potential conflict may be Indian water claims; no definitive judicial decisions have been handed down to supplement the 1908 Winters Doctrine. Methods of meeting water shortages can include interbasin transfers, additional impoundments, better knowledge of aquifer recharge systems, and forecasting and management of precipitation as well as the more exotic proposals--snowfield management, iceberg towing, and undersea aqueducts. The most practical means of saving water was judged to be demand reduction by full-cost pricing and more reuse and recycling. The water allocation process must be improved to reflect the actual conditions in the west and must not be used to manipulate land use and economic development. Benefit-cost analysis should be used in the decision making process, although this method is not without difficulties. (Cassar-FRC)

ENVIRONMENTAL IMPACT ASSESSMENT OF CHINA'S WATER TRANSFER PROJECT,
Research Inst. on Environmental Science, Beijing (China).
C. Yiqiu.
Water Supply and Management, Vol 5, No 3, p 253-260, 1981. 1 Fig, 2 Tab.

Descriptors: *Water supply development, *Decision making, *Water transfer, Planning, Water resources development, *Water transport, Water demand, Water shortage, Pipelines, Water delivery, *China.

China's South-to-North Water project is a broad concept employing numerous pipelines for diverting water of the Yangtze river in the south to the north of the Yellow River. In 1975 the North China Plain suffered an acute water shortage, and the Eastern Line was proposed by the relevant agencies in 1976 as the first phase of the plan to be established. Since the water supply is interrelated with the regional economy and agricultural production, these factors should be considered conjunctively. An environmental impact assessment must be performed as well; it has two major purposes. The first is to assess the impacts of the proposed projects on the environment, and the second is to select alternatives which might achieve the same goal as the proposed project, while minimizing any harmful effects. The material and technical data presently available for such assessments is quite limited. Thus the alternative to the Eastern Line, the Middle Eastern Line, is being left in its preliminary form. However, the general trend is clear: by taking the Middle Eastern Line as the first phase projct for diverting water of the Yangtze River to the north of the Yellow River, both capital cost and annual operating cost can be economized, as compared with the Eastern Line alone. The cost/benefit ratio will be much lower than that of the Middle Line alone. Most of the environmental problems inherent in the Eastern Line can be avoided. The Middle Eastern Line will be able to accommodate changes in the future. (Baker-FRC)

SMALL-SCALE HYDRO IN NEW ENGLAND: 1960-1976,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Civil Engineering.
P. H. Kirshen.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY1, p 31-39, May, 1981. 2 Fig, 2 Tab, 10 Ref.

Descriptors: *Hydroelectric power, *Time series analysis, *Reviews, Hydroelectric plants, Electric power production, Water resources development, *New England, Dams, Dam effects, Powerplants, Electric powerplants.

A review of the small-scale hydropower (SSH) plants in New England from 1960-1976 is presented by a time series analysis as part of a project to study the obstacles and incentives to the development of such facilities. Since 1960, the installed conventional hydroelectric capacity of the United States has increased steadily, while the total number of plants has decreased. SSH in New England has steadily decreased from 828 megawatts in 1960 to 750 megawatts in 1976. However, the average plant size in New England in 1976 was decreased over average sizes for 1960. Large-scale hydroelectric power (LSH) in New England is used primarily for peak production, while SSH is used for smaller projects. As the price of fossil fuels continues to increase, so does the demand for hydroelectric power. Industrial use of SSH has declined, while the interest of municipalities and rural electric cooperatives in SSH has expanded. A potential 1,000 megawatts of unharnessed SSH exists at nongenerating dams in New England. To

expedite licensing processes to take advantage of these sites, several federal and private institutions are studying developmental strategies to be considered by environmental policymakers. (Geiger-FRC)

DOMESTIC WATER SUPPLIES FOR POWER PLANT COOLING,
Technion-Israel Inst. of Tech., Haifa.
G. Sinai, W. A. Jury, and L. H. Stolzy.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY1, p 149-165, May, 1981. 7 Fig, 4 Tab, 23 Ref.

Descriptors: *Environmental effects, *Cooling water, *Thermal pollution, Water cooling, *Powerplants, Electric powerplants, Waste heat, Heated water, Thermal capacity, Water pollution effects, Conveyance structures, Aqueducts.

The once-through conveyor (OTC) method for powerplant cooling which utilizes water from large domestic networks close to the site of the powerplant is described. The OTC system siphons water from the domestic system and passes it once through the power plant condenser and returns the slightly warmed water to a point downstream from the intake area. The OTC system is proposed as a feasible source of cooling water which could meet the anticipated expasion rates of electrical power plants in the western United States. No adverse environmental effects are expected from this inland cooling system, and the OTC method is very inexpensive to construct and operate. Estimations of thermal capacity of major water supply systems in the Southwest show that such states as Arizona and California are already in excess of the anticipated demand for additional electricity generation in the near future. It was suggested that new powerplants be located along large aqueducts of these states to utilize their thermal cooling capacity in OTC systems. (Geiger-FRC)

WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: SKAGIT RIVER BASIN, WASHINGTON.
Federal Energy Regulatory Commission, San Francisco, CA. Office of Electric Power Regulation.
Available from Supt. of Documents, GPO, Washington, DC 20402. Report FERC-0057, August 1980. 83 p, 22 Fig, 14 Tab, 5 Ref.

Descriptors: *Water resources development, *Hydroelectric plants, *Electric power production, *Economic feasibility, *Flood control, Project planning, Flood damage, Dam construction, Water supply, Water demand, *Skagit River basin, Washington.

The Skagit River is about 163 miles long, and the basin has an area of 3,105 sq miles, of which 381 sq miles are in Canada. There are six hydroelectric generating projects on the river, with an average annual generation of 3,061 gigawatt-hours. The Ross Reservoir and Upper Baker project are used for flood control, regulating 41% of the drainage basin. Significant flood damage continues to occur annually. An addition of 121 ft to the height of the Ross Dam has been authorized. Surface water supplies are capable of exceeding municipal and industrial needs through the year 2020, and surface and groundwater sources are capable of meeting anticipated demands for irrigation water. All the projects are in good physical condition. Their continued use is economically useful, and some expansion seems feasible, if reregulation of flows from the dams is provided, and if a demand for capacity develops. (Brambley-SRC)

REPORT OF THE ANNUAL YIELD OF THE ARKANSAS RIVER BASIN FOR THE ARKANSAS RIVER BASIN COMPACT, ARKANSAS--OKLAHOMA, 1980 WATER YEAR,
Geological Survey, Little Rock, AR. Water Resources Div.
G. L. Ducret, Jr.
Geological Survey Open-File Report 81-208, 1981. 25 p, 1 Fig, 3 Tab, 3 Ref.

Descriptors: *Interstate compacts, *Interstate rivers, *Arkansas, *Oklahoma, *Streamflow, Flow rates, Gaging stations, Water yield, Runoff, Reservoir storage, *Arkansas River basin.

The computed annual yield and deficiency of the subbasins as defined in the Arkansas River Compact, Arkansas-Oklahoma, are given in tables. Actual runoff from the subbasins and depletion caused by major reservoirs in the compact area are also given in tabular form. Monthly, maximum, minimum, and mean discharge is shown for the 15 streamflow stations used in computing annual yield. (USGS)

GROUND WATER CONFLICTS AND BARRIERS,
Arizona Univ., Tucson. Law School.
R. E. Clark.
Available from the National Technical Information Service, Springfield, VA 22161 as CONF-800137, Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U.S. Department of Energy's National Workshop, January 29-31, 1980, Albuquerque, New Mexico. Department of Energy Report CONF-800137, November 1980. p 49-63, 43 Ref.

Descriptors: *Groundwater potential, *Water law, *Legislation, Groundwater management, State jurisdiction, Federal jurisdiction, Public rights, Water rights.

Three main areas of tension involving old ground water claims, emerging rights, and statutory provisions for transfers to different uses and places of use are outlined, with primary emphasis on the western U.S. The three areas are state law, U.S. claims and reserved rights, and intrastate and interstate opportunities. Water law is mainly property law and almost entirely state law, with ground water law being even more local than surface water law, and being developed much later. Weaknesses in ground water law include conflict over public versus private rights, water uses, quality, and water management. It is very difficult to enact legislation that will integrate surface and ground water management and encourage conservation, easy transfers, local management, and better water quality. The Federal Government, as owner of public lands, appropriates the water rights of these lands. These lands are under pressure for their water resources. Two complementary approaches to improving ground water law are suggested: legislation can be prepared that will confront and minimize many old conflicts, settle claims and determine rights; and procedures can be proposed for anticipating conflicts which have not reached the courts, including interstate conflicts. (Brambley-SRC)

CONFLICTS AND BARRIERS WORKING GROUP REPORT.
Available from the National Technical Information Service, Springfield, VA 22161 as CONF-800137, Price codes: A10 in paper copy, A01 in microfiche. In: Ground Water and Energy, Proceedings of the U.S. Dept. of Energy's National Workshop, Jauary 29-31, 1980, Albuquerque, New Mexico. Dept. of Energy Rept. CONF-800137, November, 1980. p 145-165.

Descriptors: *Environmental effects, *Groundwater potential, Groundwater availability, Energy sources, *Economic aspects, *Legal aspects, Political aspects, Jurisdiction, Legislation, Public opinion, Social impact, Water supply, Water demand, Water pollution, Land use, Water rights.

This group focused on identifying the nature, prevalence, and importance of conflicts that might arise, and the barriers likely to be encountered in using ground water for energy production purposes. Conflicts were categorized as institutional/political, Indian, physical, environmental, economic, and legal. The institutional/political issues arise because of competing jurisdiction over water issues, inadequate or non-existent laws, dispersion of urisdiction amony Federal and state agencies, and local public objection to development. Indian issues include problems of ownership rights, social impacts of development, division of opinion within the Indian population, and resistance to development of resources for the benefit of non-Indians. Physical issues produce conflicts over interference with shallow wells and streamflow, excessive withdrawals, demand versus supply, subsidence and salt water intrusion, and the poor quality of aquifers and their poential pollution. The environmental issues identified relate to the physical problems in terms of flow disruption, pollution, and changes in land use, and a general lack of data. Economic conflicts arise due to values assigned to water uses, costs of pollution, delays in projects, and third-party effects. Legal conflicts arise when there are competing demands on water supplies, competing values, uncertainties over water rights, and deficiencies in reallocation mechanisms, and when water quality and quantity are considered separately, and the interstate nature of many aquifers is not considered. LEGAL ASPECTS OF SUBSIDENCE DUE TO WELL PUMPING,
California Dept. of Water Resources, Sacramento.
W. Kopper, and D. Finlayson.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR2, p 137-149, June, 1981. 55 Ref.

Descriptors: *Subsidence, *Pumpage, *Legal aspects, *Judicial decisions, *Statutes, Wells, Institutional constraints, Law enforcement, Compaction, Flooding, Withdrawal, Drawdown, Groundwater storage, Available water, Aquifers, Economic aspects, Land subsidence.

The legal roots of the United States' 'laissez faire' attitude toward groundwater pumpage and subsidence are discussed. Some of the legal precedents which indicate a shift in policy toward holding pumpers liable for subsidence are identified, and innovative programs for the management of groundwater are reviewed. Most early cases endorsed the English common law rule and the principle of 'damnum absque injuria', or no remedy under the law for injury. A restatement of Torts II in 1969 provided a foundation for interpreting liability to include subsidence. The largest damage suit for subsidence related to pumpage was the United States Versus Anchor Oil. It provided numerous technical reports and briefs which are useful. However, the case did not go to trial. A landmark decision in Texas, Coastal Industrial Water Authority Versus W. B. York, held that a property owner did not lose title to property that became submerged. Subsequent cases in Texas contained language indicating that the court would recognize and apply the law of negligence along with willful waste and malicious injury as limitation on the existing rulings. Model legislation based upon local control of groundwater has been developed in California to address a need for basin management. The proposed legislation gives the management authority broad powers to implement various activities. (Titus-FRC)

ties, Organic compounds, Filtration, Oxidation, Biodegradation, Activated carbon, Carbon, Adsorption, *Wastewater treatment, Effluents.

At present, in order to comply with restrictions laid down by the Clean Water Act Amendments of 1977, the idea prevails of developing a separate treatment model for each nonpesticidal toxic organic compound, based on fundamental physical and chemical data. Based on experience with evaluating treatment processes, the following five unit treatment processes were used in this investigation: steam- or air-stripping, oil/water separation, filtration on diatomaceous earth or dual media, biochemical oxidation, and activated-carbon adsorption. These suggested potential treatment processes were separately applied to treatment models for each pollutant considered. Steam stripping possibilities are determined by the boiling point of the organic contaminant. Oil-water separation is a good procedure for compounds having relatively low solubilities in water. Separation is achieved by means of API separation or dissolved air flotation. Filtration is used for compounds having low water solubilities and tending to be highly adsorptive on particulate matter, organic or inorganic. Biochemical oxidation can reduce an influent concentration of about 100 mg/liter for phenols to an effluent concentration of 50 micrograms/liter, maximum. Carbon adsorption is particularly effective for compounds of higher molecular weight, lower polarity, increasing hydrocarbon unsaturation, and aromatic structure. Pollutant solubility in water may be associated with entropy, which opposes the driving force for removing the substance from water. This is particularly evident when phenolic and nitrogen-containing compounds are considered. (Baker-FRC)

A 201 POLLUTION CONTROL PLANNING TRAGEDY,
R. E. Wallace.
Public Works, Vol 111, No 1, p 54-60, January, 1980. 2 Fig.

Descriptors: *Political aspects, *Governmental interrelations, *Financing, Wastewater treatment facilities, *Northwest Hillsborough County, *Florida, Water pollution control, Water policy, Planning, Grants, Federal Water Pollution Control Act, Economic aspects, Government supports.

The sequence of events in the Section 201 (Federal Water Pollution Control Act) funding of the Northwest Hillsborough County, Florida, wastewater treatment facilities is detailed, starting in 1970 when the Board of County Commissioners decided to acquire private franchises and move toward a regional wastewater treatment system. The original 1973 plans called for $22 million in capital expenditures and engineering fees. As a result of delays and intergovernmental confusion, actual costs escalated to $49 million. Construction finally started in March 1979, with completion scheduled for March 1980. The author places the blame for the County's problems on overworked grant administrators, poorly written regulations and guidelines, constantly changing decisions, involvement of too many agencies and political bodies, lack of attention to nonpoint sources, too much reliance on computer models, and lack of agreement on what constitutes pollution. THE U.S. GEOLOGICAL SURVEY COAL HYDROLOGY PROGRAM AND THE POTENTIAL OF HYDROLOGIC MODELS FOR IMPACT ASSESSMENTS,
Geological Survey, NSTL Station, MS. Water Resources Div.
W. H. Doyle, Jr.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $7.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-542, 1981. 56 p, 4 Fig, 5 Tab, 29 Ref.

Descriptors: *Coal, *Hydrologic models, *Strip mines, *Surface water, Mathematical models, Simulation, Coal mining, Soil erosion, Evaluation, Small watersheds, *Tennessee, *Indiana, Public Law 95-87, Geological Survey Coal Hydrology Program.

A requirement of Public Law 95-87, the Surface Mining Control and Reclamation Act of 1977, is the understanding of the hydrology in actual and proposed surface-mined areas. Surface-water data for small specific-sites and for larger areas such as adjacent and general areas are needed also to satisfy the hydrologic requirements of the Act. The Act specifies that surface-water modeling techniques may be used to generate the data and information. The purpose of this report is to describe how this can be achieved for smaller watersheds. This report also characterizes 12 'state-of-the-art' strip-mining assessment models that are to be tested with data from two data-intensive studies involving small watersheds in Tennessee and Indiana. Watershed models are best applied to small watersheds with specific-site data. Extending the use of modeling techniques to larger watersheds remains relatively untested, and to date the upper limits for application have not been established. The U.S. Geological Survey is currently collecting regional hydrologic data in the major coal provinces of the United States and this data will be used to help satisfy the 'general-area' data requirements of the Act. This program is reviewed and described in this report. (USGS)
W82-00429

SUMMARY OF THE NEW ENGLAND CONFERENCE ON LEGAL AND INSTITUTIONAL INCENTIVES TO SMALL-SCALE HYDROELECTRIC DEVELOPMENT, JANUARY 30-31, 1979, BOSTON, MASSACHUSETTS.
Franklin Pierce Law Center, Concord, NH. Energy Law Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/RA/04934-03, Price codes: A04 in paper copy, A01 in microfiche. Department of Energy Report DOE/RA/04934-03, May 1980. 74 p, 47 Ref, 5 Append.

Descriptors: *Hydroelectric power, *Institutional constraints, *Federal jurisdiction, *State jurisdiction, *Regulations, Water use, Economic aspects, Model studies, Policy making, Financing, Subsidies, *New England.

Workshops were held addressing the topics: Federal regulatory systems; state regulatory systems; the economics of small-scale hydroelectric development; and systems dynamics and the systems dynamics model. Problems discussed at the Federal workshops included definitions with the Public Utilities Regulatory Policies Act (PURPA), streamlining the regulatory systems, and conflicts over competing uses of water. The states workshops discussed these topics and concern for markets, the problems of incentives for hydro development, and local processes. The economics workshops discussed the importance of determining a supply curve for small-scale hydro, and the establishment of an energy futures market in small-scale hydro. The systems workshop demonstrated how the model HYDRO I can be used in policy analysis and to predict the amount of small-scale hydro in New England over the next 20 yrs. It was suggested that the Federal Energy Regulatory Commission be able to approve a state hydro licensing plan, and then defer licensing of small-scale hydro projects to the state. Credits and allowances should be permitted for the financing of fish passage ways. State licensing reform may take the form of lead agency licensing, the removal of small-scale hydro from state utility regulations and tax laws, and provision of direct subsidies and other incentives. (Brambley-SRC)
W82-00447

EXECUTIVE SUMMARY, LEGAL OBSTACLES AND INCENTIVES TO SMALL-SCALE HYDROELECTRIC DEVELOPMENT IN THE SIX MIDDLE ATLANTIC STATES.
Franklin Pierce Law Center, Concord, NY. Energy Law Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/RA/04934-06, Price codes: A04 in paper copy, A01 in microfiche. Department of Energy Report DOE/RA/04934-06, May 1980. 68 p, 6 Fig.

Descriptors: *Hydroelectric power, *Legal aspects, *Legislation, *State jurisdiction, *Regulations, *Economic aspects, Dams, Water rights, Taxes, Competing use, Economic development, Delaware, Maryland, New Jersey, New York, Pennsylvania, Virginia.

Executive summaries of the regulation of small dams are presented for Delaware, Maryland, New Jersey, New York, Pennsylvania, and Virginia. The water laws of each state are reviewed briefly as they pertain to riparian rights, navigable waters, natural flow doctrine, reasonable use, and the presence or absence of a Mill Dam Act. Direct regulation of small-scale hydroelectric projects is the responsibility of a number of state agencies and commissions, and of municipalities through zoning regulations. The projects may be affected by indirect regulations such as energy policy, protection of historic sites, wild and senic river designation, water quantity or quality requirements, wetlands protection, soil and water conservation, recreational facilities and fish and game projects, and endangered species protection. Finanical considerations include both taxation and rate setting powers vested in the states and their agencies, and the provision of various forms of financial assistance to promote economic growth and employment. A flow diagram for regulation is given for each state. All of state regulations interrelate with Federal regulations and may be in conflict with them. Laws such as the Clean Water Act and the Public Utilities Regulatory Policies Act have particular impact. (Brambley-SRC)
W82-00448

SUMMARY OF THE MIDWEST CONFERENCE ON SMALL-SCALE HYDROPOWER IN THE MIDWEST: AN OLD TECHNOLOGY WHOSE TIME HAS COME.
Franklin Pierce Law Center, Concord, NH. Energy Law Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/RA/04934-05, Price codes: A07 in paper copy, A01 in microfiche. Department of Energy Report DOE/RA/04934-05, May 1980. 147 p, 4 Fig, 3 Tab, 3 Ref.

Descriptors: *Legal aspects, *Hydroelectric plants, *Economic aspects, *Institutional constraints, Computer models, Financing, Permits, Licensing, Dams, Midwest.

The conference focused on the legal and institutional barriers to small scale hydroelectric dam development in the Mid-west. Two of the workshop sessions discussed problems and policy responses raised by state and federal regulation, while the remaining two dealt with economic issues confronting small scale hydroelectric development and the operation and usefulness of the systems dynamics model developed by the Thayer School of Engineering. The main problems with state regulation concern the time spent on obtaining a permit and the unnecessary duplication of effort because of overlapping or parallel federal requirements. There is a need for a simplified and expeditions licensing process coordinated by a

single licensing agency. Central to the issues surrounding federal regualtion was the need to coordinate state and federal activities. It was suggested that the following features be added to the systems dynamics model: inflationary effects of licensing delays; individuals developing small scale hydroelectric sites; impacts of state laws and administration; cost of complying with federal regulations; national costs of policies as well as small scale hydroelectric development benefits; competition among various types of developers to develop a site; and impact of coordinated use of a series of dams. A major economic issue is the price to be paid to the small developer for power. Financing small scale hydroelectric projects is another major issue. Although hydroelectric generation has proven to be reliable, the overall risk of any small scale hydroelectric development is high, due to the leverage ratio, payback period and overall return, institutional uncertainties and form of power sales. (Moore-SRC)
W82-00449

LEGAL OBSTACLES AND INCENTIVES TO THE DEVELOPMENT OF SMALL SCALE HYDROELECTRIC POWER IN KENTUCKY.
Franklin Pierce Law Center, Concord, NH. Energy Law Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/RA/04934-10, Price codes: A06 in paper copy, A01 in microfiche. Department of Energy Report DOE/RA/04934-10, May 1980. 106 p, 118 Ref.

Descriptors: *Hydroelectric plants, *Legal aspects, *Water rights, *Dams, Institutional constraints, Water rights, Riparian rights, Water quality, Construction, Taxes, Financing, Utilities, *Kentucky.

Development of small scale hydroelectric sites in Kentucky involves interaction with all levels of government; Federal, State and local. The developer must not only obtain the rights to the dam structure itself and the land it is on, but must also obtain the rights to receive and impound the water, to raise and lower the water level in the reservoir, and the right to run transmission lines across neighboring land. In Kentucky, a riparian owner may not unreasonably change the natural flow of water so as to cause substantial damage to a lower riparian owner. Riparian rights on a navigable watercourse are subordinate to the public rights to navigate such waters and to make improvements in aid of such navigation. A stream is navigable by law in Kentucky if it can float logs downstream during spring high waters. The most significant department concerned with dam construction, maintenance and operation is the Department for Natural Resources and Environmental Protection (NREP). NREP has the power to prevent, abate and control water pollution. The Secretary of the department is authorized to examine and approve or disapprove all applications for dam construction permits not otherwise excepted, and establishes standards for dam safety. All energy utilities are subject to the various requirements of the Energy Commission, but developers of hydroelectric power for wholesale use or for their own are not subject to the Energy Commission. Loans or grants may be available from the Kentucky Development Finance Authority, and Business Development Corporations. The hydroelectric developer will have to pay property taxes, income taxes, and sales taxes, as well as special taxes for dealing in electricity. (Moore-SRC)

WATER REGULATIONS,
J. Josephson.
Environmental Science and Technology, Vol 15, No 6, p 620, 1981.

Descriptors: *Federal jurisdiction, *Water quality standards, *Water pollution control, Economic aspects, Cost analysis, Legal aspects, Regulations, Pollutants.

Many proposed revisions to the Clean Water Act will be reviewed by the Congress when the Act is considered for reauthorization in 1981. These proposed revisions are designed to increase the flexibility and enhance the cost-effectiveness of water pollution criteria and standards. This would be accomplished primarily by ending the application of uniform criteria and standards to all water bodies and substituting regulations which consider the nature and uses of the receiving water, including the ability of the waterway to handle pollutants. Other suggestions include greater input by scientists into the development and documentation of standards and increased responsibility on the part of the states for water quality control, with a reduced Federal role. Increased consideration of cost-benefit relationships is also encouraged. (Carroll-FRC)

6F. Nonstructural Alternatives

FLOOD FORECAST AND WARNING SYSTEM EVALUATION, SUSQUEHANNA RIVER BASIN, NEW YORK, PENNSYLVANIA AND MARYLAND.
Susquehanna River Basin Commission, Harrisburg, PA.
Report prepared for Army Corps of Engineers, Baltimore District, January, 1979. 137 p, 11 Fig, 8 Tab, 49 Ref, 5 Append.

Descriptors: *Flood forecasting, *Flood protection, *Warning systems, Flood damage, Reservoir operation, Flood control, Communication, Nonstructural alternatives, Data collections, Flash floods, *Susquehanna River basin, New York, Pennsylvania, Maryland.

Following the devastation resulting from Tropical Storm Agnes in June, 1972, the Corps of Engineers was directed to conduct a Flood Control Review Study of the Susquehanna basin to determine if any improvements or additions to the existing flood control system would be feasible. Flood forecasting and warning is evaluated as a flood damage reduction alternative for this basin. The river flood forecasting and warning system is operated to provide advance warning of flooding conditions which threaten human life and can cause property damage. The components of the system, some of which are operated by different levels of government, are: data collection; data assembly; forecast preparation; forecast dissemination; reservoir regulation; and local action. Problems or areas of concern identified in the Susquehanna River basin flood warning system include; speeding up the river forecasting process; increasing the reliability of the river forecasting system; improving flash flood warning; improving local response; and providing ongoing review of the forecasting system. The existing river forecasting system is too slow to provide timely flood forecasts for upstream areas on main rivers. It sometimes takes over 6 hours to assemble data, transfer it to the forecast center, prepare a forecast and disseminate it. A serious deficiency is the failure of the telephone communications system and its disruptive effect on the forecast system. (Moore-SRC)

6G. Ecologic Impact Of Water Development

WATER QUALITY MANAGEMENT STUDIES, LAKE SEMINOLE, APRIL-NOVEMBER 1978.
Corps of Engineers, Mobile, AL. Mobile District.
Technical Publication ACF80-10 (Final Report), September 1981. 519 p, 4 Fig, 16 Tab, 70 Ref, 13 Append.

Descriptors: *Water quality management, *Reservoirs, *Hydrologic data, *Sediments, *Biological samples, Limnology, Eutrophication, Turbidity, Iron, Mixing, Nutrients, Productivity, Zooplankton, Algal growth, Climatology, Biomass, Reservoir operation, Macrophytes, *Lake Seminole, Tributaries, Georgia, Florida, Alabama.

The purpose of Phase I was the establishment of a comprehensive water quality, sediment, and biological data base at various sites within the impoundment, in the backwater stretches of the major tributaries, and immediately downstream of the outfall on the Apalachicola River. This data base is to be utilized for the combined purposes of future reference, guidance in the improvement of reservoir operations, facilitation of coordination with state agencies in the implementation of watershed pollution control measures, and identification of significant water quality problems. Meteorological, hydrological, water quality, sediment, and biological data were obtained at a total of 19 main sampling stations in Lake Seminole, the Chattahoochee River, the Flint River, Spring Creek, Fish Pond Drain, and the Apalachicola River during 6 sampling cycles from April 17, 1978 through November 30, 1978. The Chattahoochee River accounted for 60-80% of the flow into the impoundment. As a result of operational procedures at the Walter F. George Lock and Dam on the Chattahoochee River upstream of Lake Seminole, flows through the Chattahoochee River impoundment arm exhibited considerable short term variation. Each of the major impoundment arms of Lake Seminole tended to be well-mixed both laterally and vertically. Average turbidity levels in the Chattahoochee River were approximately three times those in the Flint River. Concentrations of total iron at most stations during the spring and early summer months exceeded the EPA criterion of 1.0 mg/l. Based on nutrient content, the waters of Lake Seminole tended to be moderately high to highly productive with respect to the production of algal biomass. Zooplankton assemblages exhibited little variation in the number of taxa found at each station during the year. Aquatic macrophytes constituted the most conspicuous feature of Lake Seminole. Emergent and floating macrophytes covered over 40% of the total surface and nearly 100% of the surface with a depth less than 2 m. (Moore-SRC)

EFFECT OF MICROCRUSTACEANS ON BLUE-GREEN ALGAE IN FLOODED SOIL,
Cornell Univ., Ithaca, NY. Lab. of Soil Microbiology.
J. T. Wilson, S. Greene, and M. Alexander.
Soil Biology and Biochemistry, Vol 12, No 3, p 237-240, 1980. 2 Tab, 7 Ref.

Descriptors: Eutrophication, *Floodwater, *Crustaceans, Cyanophyta, Water pollution effects, *Rice, Algae, Ostracods, Waterfleas, Nitrogen, Insecticides, Grazing, *Nitrogen fixation, Soil types, Soil water, *Algal control, Grazing.

In lowlands rice paddies, nitrogen-fixing algae can be an important source of nitrogen. Grazing by microcrustaceans and other fauna of flooded soil may limit the extent of algal development and affect the amount of nitrogen fixed by the algae. Previous studies have shown that the use of lindane or parathion kills the microcrustaceans and allows algal growth to flourish. Laboratory experiments were conducted to assess the effects of controlled numbers of ostracods and waterfleas (Daphnia magna) on the growth rate and nitrogen-fixing activity of Tolypothrix tenuis and Anabaena sp. When present in large numbers, grazing ostracods suppressed growth of Anabaena sp. on flooded soil and prevented the development of T. tenuis. Large numbers of D. magna had only a slight effect on the growth rate and development of these nitrogen-fixing algae. T. tenuis was more susceptible than Anabaena sp. to the grazing of these microcrustaceans. It was suggested that microcrustaceans may play a significant role in the nitrogen fixation by algae in lowland rice growing areas. (Geiger-FRC)

POWER PLANT WATER INTAKE ASSESSMENT,
Consumers Power Co., Jackson, MI.
I. H. Zeitoun, J. A. Gulvas, and J. J. Rochow.

Environmental Science and Technology, Vol 14, No 4, p 398-402, April, 1980. 2 Fig, 2 Tab, 5 Ref.

Descriptors: *Power plants, *Environmental effects, Vegetation effects, Aquatic life, Fish, Entrainment, Impingment, Economic aspects, Decision making, Planning, Legal aspects, Regulations, *Intakes, Water intake, *Ecological effects, Ecosystems.

The total assessment of the impact of water intake by power plants should be related to its total effect on the ecological system, not solely on the numbers or weights of aquatic organisms impinged or entrained. The lack of emphasis on this aspect in the Federal Water Pollution Control Act (FWPCA) and the lack of an established set of criteria to explain or define acceptable limits of environmental impact creates perplexing situations. Alternative cooling schemes must be evaluated and compared as to their effects on all ecosystems. Acceptability of an intake should be based on prediction or detection of significant adverse changes or disruption at the ecosystem level. In many cases power plant effects are isolated and the stresses imposed on aquatic life are ignored. Attempts have been made to integrate the biotic and economic values in order to compare the environmental impact potential with the cost of an offshore intake. In examining 20 Lake Michigan power plants via this economic approach, the value of fishes lost was found to represent less than 1% of the established commercial value of fish landed during the time of the evaluation. It is concluded that the ability of the environment to resist perturbation and the existence of indigenous compensatory mechanisms must be taken into account as part of the decision making progress related to power plant operation. (Baker-FRC)
W82-00216

FINAL ENVIRONMENTAL IMPACT STATEMENT; DINKEY CREEK PROJECT NO. 2890 - CALIFORNIA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation.
Report FERC/EIS-0010, August 1980. 302 p, 21 Fig, 35 Tab, 56 Ref, 11 Append.

Descriptors: *Environmental impact statement, *Hydroelectric plants, *Dam effects, *Construction, Water quality, Turbidity, Wildlife habitats, Water pollution sources, Fish populations, Reservoirs, Benthic fauna, Spoil disposal, Planning, *Dinkey Creek project, *California.

The conventional hydroelectric project proposed for construction on Dinkey Creek, Fresno County, California would consist of: a dam and reservoir on Dinkey Creek; a power tunnel; two powerhouses; three diversion tunnels; access road; recreational facilities; and other appurtenant facilities. The total installed capacity would be 120 megawatts. Environmental impacts caused by construction and operation of the project would include: increased turbidity and loss of benthic invertebrates and fish in portions of Dinkey Creek and the diversion tributaries during construction; alteration of approximately 1,176 acres of upland valley topography; loss of productive timber land and wildlife habitat; disturbance to the existing recreational setting while construction is underway; and inundation of archeological resources. The introduction of large quantities of suspended sediments into Dinkey Creek and tributaries from excavating tunnels and from spoil deposition areas would have the greatest impact on the water quality of the project. During tunnel excavation, drilling operations would require cooling water that would be characterized by high concentrations of hydraulic oil, cement, and inorganic materials after use. In addition, ground water encountered during drilling would compound the water quality problem. (Moore-SRC)
W82-00352

FINAL ENVIRONMENTAL IMPACT STATEMENT; TERROR LAKE PROJECT NO. 2743 - ALASKA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation.
Report FERC/EIS-0026, August, 1981. 393 p, 43 Fig, 16 Tab, 59 Ref, 8 Append.

Descriptors: *Environmental impact statement, *Dam effects, *Construction, *Environmental effects, Reservoirs, Wildlife habitats, River flow, Water temperature, Diversion dams, Planning, *Terror Lake, Kodiak, *Alaska.

Kodiak Electric Association proposes to construct a 20-MW conventional hydroelectric project by using the hydroelectric potential of Terror Lake, a natural lake located in a glaciated valley, 25 miles southwest of the City of Kodiak, Alaska. The proposed development would require the construction of a 156-foot high rockfill dam, 2,100 feet in length. The 270-acre natural lake would be inundated and replaced by an 850-acre reservoir. During project operation, water would be diverted from Terror Lake Reservoir and Falls, Shotgun, and Rolling Rock Creeks, through the power tunnel and penstock, to turn generators in the powerhouse that would be located on the Kizhuyak River. Approximately 1,878 acres of land and 270 water surface acres within the Kodiak National Wildlife Refuge would be included in the project. Significant environmental impacts of the proposed project include: loss of approximately 1,080 acres of wildlife habitat; human intrusions and construction activities within the wildlife refuge; flow in the Terror River immediately below the dam would be reduced by up to 90%; reduced flows in the Kizhuyak River from the Shotgun and Falls Creeks Diversion Dams downstream to the powerhouse; alteration of the thermal regime of the Terror and Kizhuyak Rivers. The design of the proposal is considered to be environmentally superior to that of either of the proposed alternatives. (Moore-SRC)
W82-00353

FINAL ENVIRONMENTAL IMPACT STATEMENT; TYEE LAKE PROJECT FERC NO. 3015 - ALASKA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation.
Report FERC/EIS-0023, June, 1981. 224 p, 24 Fig, 17 Tab, 25 Ref, 6 Append.

Descriptors: *Environmental impact statement, *Hydroelectric plants, *Construction, Wildlife, Aquatic habitats, Water temperature, Wetlands, Environmental effects, Flow discharge, Water conveyance, Intakes, Transmission lines, Planning, Baseline studies, *Tyee Lake Project, Wrangell, *Alaska.

The proposed 20 MW hydroelectric project on Tyee Creek in Tongass National Forest near Wrangell, Alaska, would require: a lake tap intake structure in Tyee Lake at approximately 1,230 ft elevation; approximately 8,700 ft of shaft and tunnel for water conveyance; a powerhouse near the Bradfield Canal; approximately 1,100 ft of channel from the powerhouse tailrace to Airstrip Slough; 69 miles of overhead and 12 miles of submarine transmission line; approximately 1 mile of access road; and other appurtenant facilities. Development of the proposed Tyee Lake Project would result in the following unmitigated environmental impacts: removal of 490 acres of commercial forest land; some degradation of visual resources related to the proposed transmission line; up to a 92% reduction in the discharge to Tyee Creek, and associated reduction in aquatic habitat; changes in the thermal regime of Airstrip Slough; disturbance of wetlands near Airstrip Slough; and human intrusion on wildlife resources during construction. The Tyee Lake Project is recommended as proposed, with mitigative measures. (Moore-SRC)
W82-00354

FINAL ENVIRONMENTAL IMPACT STATEMENT FOR PROPOSED SEWERAGE FACILITIES IN THE MARION COUNTY LAKE IMPROVEMENT DISTRICT, MARION COUNTY, KANSAS.
Environmental Protection Agency, Kansas City, MO. Region VII.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-160145, Price codes: A11 in paper copy, A01 in microfiche.
Report EPA-907/9-80-004, December, 1980. 246 p, 12 Fig, 30 Tab, 80 Ref, 5 Append.

Descriptors: *Environmental impact statement, *Marion County Lake, Kansas, *Sewer systems, *Wastewater facilities, *Domestic wastes, Storage tanks, Septic tanks, Economic impact, Environmental effects, Social impact, Water quality, Population dynamics, Leachates, Flora, Fauna, Hydrology, Geology, Soils.

The Marion County Lake Improvement District is a small residential community, surrounding the 150 acre lake, in which the sewerage facilities consist entirely of on-site systems - septic tanks, holding tanks, and privies. This Environmental Impact Statement examined five alternatives for the improvement of sewerage facilities: no action; facility plan; down-sized facility plan; down-sized total retention lagoon; and limited public on-site systems. The environmental, social, and economic impacts of each of these alternatives were evaluated, along with appropriate mitigation measures. Extensive investigations were conducted into population projections; hydrology, geology, and soils; flora and fauna; septic leachate; and cost effectiveness. Based on these investigations the EPA has determined that sufficient water quality problems do not exist to merit funding under the Construction Grants program of the Clean Water Act of 1977, and therefore no further grant will be awarded for this project. (Brambley-SRC)
W82-00355

FINAL ENVIRONMENTAL IMPACT STATEMENT, CITY OF PORTAGE WASTEWATER SYSTEM, COLUMBIA COUNTY, WISCONSIN.
Environmental Protection Agency, Chicago, IL. Region V.
Report, July, 1980. 362 p, 23 Fig, 31 Tab, 142 Ref, 6 Append.

Descriptors: *Environmental impact statement, *Portage, Wisconsin, *Secondary wastewater treatment, *Wastewater facilities, *Wastewater disposal, Air pollution, Geology, Soils, Groundwater, Flora, Fauna, Surface water, Land use, Flood plains, Social impact.

A 201 Facilities Plan was prepared for Portage, Wisconsin, that concluded that a new secondary treatment facility adjacent to the Wisconsin River was necessary to replace the old and hydraulically overloaded facility now located on the Fox River. The Environmental Impact Statement addresses the impacts on the environment that would result from each of eight alternate sites, and the cost for each site. The environmental parameters considered are air quality and sound; geology, soils, and groundwater; surface waters; terrestrial and aquatic flora (including wetlands); terrestrial and aquatic fauna; cultural resources; socioeconomic characteristics; agricultural land and land use; flood plains; and energy and chemical requirements. It is concluded that secondary effluent should be discharged to the Wisconsin River from a new site which avoids destruction of wetlands and other environmental problems. Some mitigative measures are recommended to overcome problems resulting from heavy metals, residual PCB sources, and construction dust, noise, nuisance, erosion and sedimentation. An archaeological survey was used to identify historic places likely to be affected by waste facility construction. (Brambley-SRC)

FINAL ENVIRONMENTAL IMPACT STATEMENT; SOUTH FORK AMERICAN RIVER DEVELOPMENT, UPPER MOUNTAIN PROJECT NO. 2761 - CALIFORNIA.
Federal Energy Regulatory Commission, Washington, DC. Office of Electric Power Regulation.
Report FERC/EIS-0020, May 1981. 304 p, 37 Fig, 43 Tab, 141 Ref, 6 Append.

Descriptors: *Environmental impact statement, *Hydroelectric plants, *Dam effects, Construction, *Conveyance structures, Reservoirs, Fish populations, Social aspects, Economic aspects, Wildlife habitats, Dam construction, Environmental effects, Recreation facilities, Stream discharge, Sedimentation rates, Planning, *South Fork American River Project, *California.

El Dorado County Water Agency and El Dorado Irrigation District filed an application for a license for the proposed South Fork American River Development, Upper Mountain Project, a conventional hydroelectric and water supply project. The issuance of a license would authorize the construction of: two major diversion structures (dams), one each on the upper South Fork American River and the Silver Fork American River; seven minor diversion structures on tributaries of the South and Silver forks of the American River; a major diversion structure and storage reservoir on Alder Creek; approximately 34 miles of water conveyance structures; three powerhouses; approximately 29 miles of transmission lines; three new access roads; new and improved recreational facilities; and other appurtenant facilities. The total installed generating capacity would be 110.4 MW, with an annual average generation of approximately 470,000 MWh. Environmental impacts caused by construction and operation of the project would include: alteration of existing stream hydraulic parameters, flow rates, sedimentation rates, water temperatures, species composition, and growth and population sizes of fish; the withdrawal of approximately 2850 acres from timber production; the permanent loss of approximately 2000 acres of wildlife habitat; possible decrease in the population size of at least one deer herd; disturbance to existing recreational use of the area during construction; disturbance of normal highway traffic during construction; temporary impacts to air quality and ambient noise levels during construction; direct and indirect impacts to cultural resource sites, direct and indirect socioeconomic effects in El Dorado County; and changes in the characteristics of visual and recreational resources. (Moore-SRC)
W82-00367

FINAL ENVIRONMENTAL IMPACT STATEMENT; SOUTH TAHOE PUBLIC UTILITY DISTRICT AND DOUGLAS COUNTY SEWER IMPROVEMENT DISTRICT NO. 1, APPENDIX B: MITIGATION PROGRAM.
Sedway/Cooke, San Francisco, CA.
Environmental Protection Agency Report, May 1981. 439 p.

Descriptors: *Environmental impact statement, *Lake Tahoe, California, *Environmental protection, *Wastewater facilities, Erosion control, Runoff, Land use, Forest management, Water quality control, Monitoring, Environmental quality.

The Mitigation Task Force, which was created to coordinate the actions of the agencies with authority to reduce the environmental impacts of the proposed expansion of the South Tahoe Public Utility District, has identified 97 measures to be implemented by 28 agencies. The measures and the agency responsible for implementation of each measure are presented in a matrix. There are 13 areas of impact: water resources and water quality; geology and soils; biology; noise; meteorology and air quality; visual resources; land use and housing; transportation; recreation; public services/fiscal concerns; utilities; cultural, archeological and historical resources; and the Carson Valley. In the water resources and quality category there are sixteen required measures in the areas of erosion and drainage projects, on-site runoff controls, development restrictions, and forest practices; and one recommended measure, monitoring. For each measure, the statements of the responsible agencies are given, and implementation statements from all agencies are also presented. (Brambley-SRC)

7. RESOURCES DATA

7A. Network Design

EVALUATION OF GROUND-WATER MONITORING NETWORK, SANTA CRUZ COUNTY, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
G. G. Blankenbaker, and C. D. Farrar.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $7.50 in paper copy, $4.50 in microfiche. Geological Survey Open-File Report 81-139 (WRI), April 1981. 20 p, 1 Fig, 2 Plates, 6 Tab, 10 Ref.

Descriptors: *Groundwater, *Network design, *Monitoring, *Water quality, Observation wells, Water level, Groundwater storage, Saline water intrusion, Forecasting, Evaluation, *California, *Santa Cruz County.

The Santa Cruz County Flood Control and Water Conservation District seeks to improve the existing network of observation wells to monitor water levels and ground-water quality in the Pajaro Valley subarea and the Aptos-Soquel, San Lorenzo, and Santa Cruz Coastal subbasins in California. The proposed network, consisting of 92 wells, is designed to monitor changes in storage and quality of ground water resulting from climatic changes and management-induced stresses. In the proposed network, water levels in all wells would be measured semiannually, in April and September, and monthly in a few key wells. The water-level measurements would provide data that could be used to determine changes in ground-water storage. In addition to the currently monitored characteristics--temperature, specific conductance, pH, and chloride ion concentration--inclusion of annual sampling and analysis for major ions and nutrients is proposed. The network would also include sampling and analysis for trace elements once every 4 years. More frequent analyses are proposed in areas where water-quality problems are known to exist or where potential water-quality problems are recognized. Analyses for major ions, nutrients, and trace elements are included in the proposed network to provide baseline data for monitoring long-term changes in water quality and to detect any unexpected changes in quality. (USGS)

7B. Data Acquisition

A QUALITATIVE APPRAISAL OF THE HYDROLOGY OF THE YEMEN ARAB REPUBLIC FROM LANDSAT IMAGES,
Geological Survey, Reston, VA. Water Resources Div.
M. J. Grolier, G. C. Tibbitts, Jr, and M. M. Ibrahim.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $18.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 80-565, 1981. 103 p, 6 Fig, 1 Plate, 2 Tab, 34 Ref, 3 Append.

Descriptors: *Arid lands, *Remote sensing, *Foreign research, *Drainage systems, Land use, Irrigation effects, Vegetation, Ephemeral streams, Intermittant streams, Surface-groundwater relations, Groundwater potential, Water quality, Hydrologic cycle, Evaluation, Water resources development, Planning, *Yemen Arab Republic, Landsat, Arabi-

an Peninsula, Red Sea, Tihama, Satellite technology.

Six series of Landsat-1 and Landsat-2 images taken between 1972 and 1976 were analyzed to describe the flow regimens of streams and the regional distribution of vegetation in the Yemen Arab Republic. The findings provide a factual basis for planning a surface-water data collection program, and for preparing maps of plant distribution and agricultural land use. They lay the foundation for modernized water development, for effecting a program of country-wide water management. The work was undertaken as part of the program of the U.S. Agency for International Development with the cooperation of the Yemen Mineral and Petroleum Authority, Ministry of Economy. A false-color composite mosaic of the nine images which cover the country was prepared using Landsat 1 images taken at relatively low sun-angle in winter 1972-73. Catchment areas and the major drainage basins of the country were delineated on this mosaic. In order of increasing water availability, the four catchment areas of the YAR are: Ar Rub al Khali, Wadi Jawf (Arabian Sea), Red Sea, and Gulf of Aden. Most streams are ephemeral. No lakes were detected during the period under investigation, but sebkhas--salt flats or low salt-encrusted plains--are common along the Red Sea coast. In spite of resolution and scale constraints, streamflow was interpreted as perennial or intermittent, wherever it could be detected on several Landsat images covering the same scene at seasonal or yearly intervals. Much of the land under cultivation is restricted to valley floors, and to valley slopes and irrigated terraces adjacent to stream channels. Little or no vegetation could be detected over large regions of the Yemen Arab Republic. (USGS)
W82-00022

SEASAT SAR RESPONSE FROM WATER RESOURCES PARAMETERS,
Texas A and M Univ., College Station. Remote Sensing Center.
B. J. Blanchard, A. J. Blanchard, S. W. Theis, W. D. Rosenthal, and C. Jones.
Final Report 3891, June, 1981. 41 p, 11 Fig, 1 Tab, 7 Ref.

Descriptors: *Soil water, *Remote sensing, Flooding, *Satellite technology, Forests, Corn, Alfalfa, Milo, *Vegetation, Radar, Agriculture, Furrows.

An initial investigation of the SEASAT synthetic aperture radar (SAR) data was directed toward estimation of soil moisture; vegetation type, surface roughness due to tillage and flood extent under forest canopy. The SAR response was validated with a series of data sets from an L-band scatterometer flown in the NASA C-130 aircraft. Soil moisture in the surface 15 cm from fields of milo, alfalfa and bare soil produce similar differences (9 db range) in the scattering coefficient from both systems. Most agricultural vegetation was effectively transparent and was penetrated by this wave-length. Corn produces exceptionally high returns; however, there was evidence that tillage roughness could be detected through the corn canopy. Forest canopy, in contrast, produces moderate returns except when the forest floor is flooded. Flooded forest produced 3 to 6 db higher scattering coefficients than non-flooded forest for both the SAR and scatterometer. There was no detectable difference in response from conifer and deciduous forest canopy. Circular tillage patterns were used to illustrate the look angle dependence of row direction effects on the radar return. Roughness due to tillage can produce as much as 12 db increase in return. The SEASAT SAR produced valuable information and in some instances would enable estimates of parameters that are not feasible with any other known system.

SEDIMENT TRAP DYNAMICS AND CALIBRATION: A LABORATORY EVALUATION,
Lamont-Doherty Geological Observatory, Palisades, NY.
W. Gardner.
Journal of Marine Research, Vol 38, No 1, p 17-39, 1980. 5 Fig, 5 Tab, 41 Ref.

Descriptors: *Sediments, *Experimental design, Calibration, Turbulence, *Particle size, *Trap efficiency, Lakes, Estuaries, Laboratory equipment, Technology, Trapping, Flow, Currents, Fluvial sediments, Deposits.

The flow dynamics and particle trapping characteristics of several designs of sediment traps were investigated using dye, seawater, and deep sea lutite in a recirculating flume and fish tank at velocities of 0, 4, and 9 cm per second. Particles are collected through a process of fluid exchange rather than by falling into the trap. The efficiency of the trap is therefore a function of the residence time and circulation pattern of fluid, processes controlled by trap geometry and current velocity. Cylinders trap particles in the closest agreement with the sediment deposition rate in the flume. Funnels undertrap, but their efficiency may be improved with baffles at the top of the funnel. Containers with narrow mouths and wide bodies overtrap at an unpredictable rate. (Titus-FRC)
W82-00104

FIELD ASSESSMENT OF SEDIMENT TRAPS,
Lamont-Doherty Geological Observatory, Palisades, NY.
W. D. Gardner.
Journal of Marine Research, Vol 38, No 1, p 41-52, 1980. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Sediments, Trapping, *Trap efficiency, On-site tests, *Particle size, *Flumes, Field tests, Flow, Velocity, Calibration, Funnels, Coastal waters, Tidal effects, Currents, Water sampling, Harbors.

Sediment traps whose particle collection abilities had been calibrated in a laboratory flume at velocities of 0, 4, and 9 cm per second were deployed in natural bodies of water to intercalibrate larger traps under current conditions ranging from tranquil to over 20 cm per second. For cylinders, the height to width ratio is the controlling factor for the mass of sediment collected. Traps can be scaled up in size and maintain a similar collection rate. Increasing current velocity will alter the collection rate of a trap in a manner which depends on the trap geometry. The size distribution of particles collected in traps is biased by trap geometry, with overefficient traps collecting more fine particles. (Titus-FRC)

MEASURING FLUMES OF SIMPLIFIED CONSTRUCTION,
Science and Education Administration, Phoenix, AZ. Water Conservation Lab.
J. A. Replogle, and A. J. Clemmens.
Transactions of the ASAE, Vol 24, No 2, p 362-366, 374, March-April, 1981. 4 Fig, 2 Tab, 16 Ref.

Descriptors: *Flumes, Flow measurement, Water measurement, Irrigation canals, Mathematical models, Channel flow, Water flow.

Mathematical modeling has provided information for design and construction of a simplified measuring flume for irrigation channels. The flumes are designed for the canal, rather than vice versa. The flumes have high submergence limits and can be used on canals that cannot tolerate much head loss. Portable aluminum or precast flumes have been constructed and installed. Three standard-sized flumes were developed for each of three canal shapes for a normal flow range, 20 to 500 liters per sec. These flumes cost about one-tenth as much as previously used measuring structures. (Cassar-FRC)
W82-00140

A MORE VERSATILE SOIL WATER SAMPLER,
North Central Forest Experimental Station, Grand Rapids, MN.
M. D. Knighton, and D. E. Streblow.
Soil Science Society of America Journal, Vol 45, No 1, p 158-159, 1981. 1 Fig, 3 Ref.

Descriptors: *Soil water, *Sampling, *Measuring instruments, Nutrients, Leachates.

The development of a versatile ceramic-cup soil water sampler which overcomes some of the limitations of previous models is reported. Having no rigid parts extending above the soil surface, this new model may be installed at shallow depths prior to such disruptive plot activities as logging which would normally destroy earlier models. The ceramic cup of the new sampler may be positioned within a few centimeters of the soil surface without the problems of instability or flow of surface water down the side of the sampler which occurred with previously existing models. Location of the ceramic cup above the sampler reservoir prevents the reverse flow of soil water through the cup which occurs if the soil dries during the sampling interval. Disadvantages of the new sampler include the need for a larger and deeper hole for installation than was necessary with the earlier sampler, resulting in more soil profile disruption; the possibility that the ceramic cup will dry out more readily because it is not in contact with the collected water; and slightly increased materials, labor, and equipment needs for construction of the sampler. Comparison of the chemistry of soil water samples collected using new samplers and the previously existing samplers indicated no significant differences in the concentrations of nitrogen, phosphorus, potassium, calcium, or magnesium nor in specific conductance. (Carroll-FRC)

BIONESS, A NEW DESIGN IN MULTIPLE NET ZOOPLANKTON SAMPLERS,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia). Marine Ecology Lab.
D. D. Sameoto, L. O. Jaroszynski, and W. B. Fraser.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 4, p 722-724, April, 1980. 2 Fig, 3 Ref.

Descriptors: *Biological samples, *Plankton nets, *Measuring instruments, Sampling, Water sampling, *Zooplankton, Nets, Data collections, Marine biology, Temperature, Conductivity, Entrainment.

A new multiple-net zooplankton and micronekton sampler (BIONESS) designed by the Bedford Institute of Oceanography is designed with a horizontal arrangement of nets to reduce the size of the mouth opening and make the structure more streamlined. Ten 1.0 sq m nets open sequentially and are towed at three knots on a conductor cable. The conductor cable is equipped with transmitters and receivers to relay information from the sampler to the ship. Sensors for temperature, conductivity, depth, illumination, pitch, roll, and yaw are featured on the BIONESS sampler along with a camera and internal and external electronic flowmeters. These features enable environmental data to be collected simultaneously with biological samples. The sampler is easier to handle than older models, and its chance for contamination by larger organisms is minimal. (Geiger-FRC)

POSSIBILITIES OF USING HELIUM AND TRITIUM SURVEYS FOR STUDYING RECHARGE CONDITIONS OF SUBSURFACE WATERS,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
V. L. Zlobina, V. S. Kovalevskii, I. K. Morkovkina, L. K. Ovchinnikova, and V. V. Romanov.

Water Resources (English Translation), Vol 7, No 1, p 73-76, January/February, 1980. 3 Fig, 4 Ref. Translated from Vodnye Resursy, No 1, p 166-170, January/February, 1980.

Descriptors: *Recharge, *Subsurface water, Water, Natural recharge, Groundwater, Helium, *Geohydrology, Tritium, Chemical composition, Chemical analysis, Water analysis, Groundwater movement, *Groundwater recharge, Tracking techniques.

A helium survey was used for detecting areas of water-bearing deposits of sedimentary rocks with maximum permeability in the Moscow territory. The principle of such a survey consists in recording the distribution of concentrations of free, mobile helium, whose main form of migration is seepage with subsurface waters in a dissolved state. Helium concentrations in subsurface waters increase with depth; thus an increase in helium concentration indicates discharge of deeper water-bearing horizons via lithologic windows and tectonic crush zones and by through-flow. A marked decrease proves the existence of inflow of infiltration, river, or ground waters, diluting the background concentrations of this element in the aquifer. Thus on the basis of helium anomalies one can detect recharge areas of the aquifer from above and below and make a quantitative evaluation of the components of the balance of the given aquifer and its change in time under the effect of exploitation of subsurface waters. Water samples were taken in 1978 from water-bearing horizons of Middle and Lower Carboniferous and partially Devonian deposits. Samples for tritium analysis were also taken. It was concluded that the use of helium and tritium surveys in complex hydrodynamic and hydrochemical settings permits the detection of possible recharge areas of subsurface waters and also areas of qualitative change in the chemical composition of these waters as well as the mapping of the contours of areas of possible activation of karst processes. AN APPRAISAL OF POND-NET SAMPLES FOR BIOLOGICAL MONITORING OF LOTIC MACROINVERTEBRATES,
Freshwater Biological Association, Wareham (England).
M. T. Furse, J. F. Wright, P. D. Armitage, and D. Moss.
Water Research, Vol 15, No 6, p 679-689, 1981. 4 Fig, 4 Tab, 22 Ref.

Descriptors: *Sampling, *Macroinvertebrates, *Classification, Monitoring, Invertebrates, Aquatic animals, Benthic fauna, Rivers, Lotic environment, Precision, Pond-net test.

The pond-net technique for sampling benthic macroinvertebrates proved suitable and reliable to use in a British national classification scheme for running water sites. In a field trial, 6 pond-net samples (3 operators, 2 samples each) of 3 min duration were taken at each of 4 sites on the River Axe, England. There were significant differences with respect to sites, operators, and site x operator interactions. There were significant interoperator differences in the number of taxa removed from samples at the family level in the sample processing stage. Nevertheless, at the species level there was strong site faithfulness for each series of 6 samples. A 3 min sample netted 62% of the families and 50% of the species caught in an 18 min sample. The results of this trial confirmed the suitability of the pond-net test for use in the classification exercise, which involves 40-60 biologists, 267 sites, and 41 rivers in Great Britain. WATER RESOURCES INVESTIGATIONS IN NEW YORK--1980.
Geological Survey, Albany, NY. Water Resources Div.
Geological Survey Open-File Report 80-1219, 1980. 68 p, 5 Fig, (Compiled by Finch, A.).

Descriptors: Reviews, *Surface water, *Groundwater, *Water quality, Bibliographics, *Projects, Publications, *New York, U.S. Geological Survey, Water Resources Division.

This report describes the water-resources investigations conducted by the U.S. Geological Survey in New York in 1980; many of these studies will continue into 1981 or longer. The Geological Survey began its water-resources studies in New York State in 1895 with a stream-gaging program in the Catskill Mountain region and entered its first cooperative program, with the Office of the State Engineer, in 1900. Since 1910, the Survey has maintained a District office in Albany to direct its water investigations within the State. A Long Island subdistrict office was established in 1932 to monitor and study the ground-water situation in this area of increasing urbanization. Subdistrict offices are also maintained in Ithaca and Albany to collect and interpret data from western and eastern New York, respectively. A field station is maintained in Potsdam to collect records in the northernmost part of the State. A bibliography of reports published or released in 1980 by the New York District is included. (USGS)

SELECTED HYDROLOGIC DATA, ARKANSAS RIVER BASIN, PUEBLO AND SOUTHEASTERN FREMONT COUNTIES, COLORADO, 1975-80,
Geological Survey, Lakewood, CO. Water Resources Div.
D. Cain, and P. Edelmann.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $33.50 in paper copy, $4.00 in microfiche. Geological Survey Open-File Report 80-1185, 1980. 233 p, 1 Plate, 20 Tab, 2 Ref.

Descriptors: *Data collections, *Water quality, *Surface water, Discharge measurement, Gaging stations, Traveltime, Nutrients, Pesticides, Trace metals, Chemical analysis, *Colorado, Pueblo County, Fremont County, *Arkansas River basin.

Selcted hydrologic data collected in 1975-80 as part of water-quality investigations by the U.S. Geological Survey in Pueblo and southeastern Fremont Counties, Colo., are presented in this report. The data, in tabular form, consist of streamflow-discharge measurements for 33 sites, channel-geometry measurements for 97 sites, traveltime data for 12 sites, and field and laboratory water-quality analyses for 194 sites. Federal, state, and local officials may find these data useful in making decisions relating to the management of water resources of the area. (USGS)
W82-00020

WATER RESOURCES OF THE SANTA YSABEL AND MESA GRANDE INDIAN RESERVATIONS, SAN DIEGO COUNTY, CALIFORNIA,
Geological Survey, Menlo Park, CA. Water Resources Div.
J. R. Freckleton.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $6.25 in paper copy, $4.00 in microfiche. Geological Survey Open-File Report 81-342 (WRI), 1981. 27 p, 1 Fig, 1 Plate, 8 Tab, 8 Ref.

Descriptors: *Hydrology, *Geology, *Water resources development, *Water supply, Groundwater, Drillers logs, Wells, Water yield, Springs, Surface water, Streamflow, Precipitation, Water quality, Chemical analysis, Potential water supply, Evaluation, *California, Santa Ysabel Indian Reservation, Mesa Grande Indian Reservation, *Indian reservations, San Diego County.

The Santa Ysabel (consisting of three tracts) and Mesa Grande Indian Reservations are in north-central San Diego County, Calif. On both reservations fractured and weathered igneous and metamorphic rocks and alluvium are water bearing; however, no wells are known to derive their water entirely from alluvium. Well yields range from 2.5 to 250 gallons per minute. Springs occur where saturated fractured or weathered material intersects the land surface. Spring discharge ranged from 0 gallon per minute (November 1979) to 9.4 gallons per minute (November 1979). Few data are available for the surface water characteristics of the study area. One-time measurements of discharge at selected stream sites were made in late November 1979 and late May 1980; discharges ranged from less than 0.01 cubic foot per second to an estimated 3 cubic feet per second. Further study of the surface-water systems would provide a basis for estimating their development potential. The existing water-supply development on the Santa Ysabel Indian Reservation is adequate for the present residents. The Mesa Grande reservation was unoccupied in 1952, was reportedly unoccupied in November 1979, and has no developed water supply. Additional water can be developed for both reservations from the igneous and metamorphic rock, from presently undeveloped springs, and from perennial reaches of the larger streams. Except for excessive iron and sodium at some ground-water sites and excessive sodium at a few surface-water sites, the water is of suitable quality for domestic and agricultural use. (USGS)

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN THE SUWANNEE RIVER WATER MANAGEMENT DISTRICT, FLORIDA, MAY 1980,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. C. Rosenau, and R. S. Milner.
Geological Survey Open-File Report 81-211 (WRI), 1981. 1 Sheet.

Descriptors: *Maps, *Aquifers, *Water level, *Potentiometric level, *Wells, Contours, Water level fluctuations, *Florida, Floridan aquifer, Suwannee River Water Management District.

A May 1980 potentiometric surface map of the Suwannee River Water Management District area, Florida, depicts water levels in wells tapping the Floridan aquifer. Compared to the May 1976 potentiometric map of the area, there are no significant differences in the general appearance of the contours. Water levels, however, are generally about 10 feet higher than in 1976 along the Suwannee River and for some 20 miles west of the river and in Gilchrist and Levy Counties to the east. (USGS)
W82-00024

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN THE NORTHWEST FLORIDA WATER MANAGEMENT DISTRICT, MAY 1980,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. C. Rosenau, and R. S. Milner.
Geological Survey Open-File Report 81-205 (WRI), 1981. 1 Sheet.

Descriptors: *Maps, *Aquifers, *Water level, *Potentiometric level, *Wells, Contours, Water level fluctuations, *Florida, Floridan aquifer, Northwest Florida Water Management District.

A May 1980 potentiometric surface map of the Northwest Florida Water Management District depicts water levels in wells tapping the Floridan aquifer prior to summer pumpage. Compared to earlier potentiometric maps of the area, there are no significant differences in the 1980 map that are the result of hydrologic conditions. The addition of numerous new monitor wells in Jackson, Calhoun, Gadsden, and Liberty Counties, however, permitted refinement or better delineation of contours and a separation of water-bearing zones of the Floridan aquifer in the latter two counties. (USGS)

WATER RESOURCES OF PRINCE WILLIAM FOREST PARK, VIRGINIA,

Geological Survey, Albany, NY. Water Resources Div.
G. A. Brown.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $2.50 in paper copy, $0.50 in microfiche. Geological Survey Open-File Report 80-964 (WRI), 1981. 2 Sheets, 13 Fig, 13 Ref.

Descriptors: *Maps, *Water supply, *Water quality, *National parks, Geohydrology, Data collections, Groundwater availability, Water level, Groundwater movement, Well yields, Surface water, Flow characteristics, Water use, Recreation facilities, *Virginia, *Prince William Forest Park.

Prince William Forest Park is in the southern part of Prince William County, Va. Its natural beauty and nearness to Washington, D.C. have made it one of the most popular recreation areas in northern Virginia. To help the National Park Service plan the development of new facilities and effectively manage its total resources, the U.S. Geological Survey made a hydrologic study of the park from October 1972 to November 1975. The overall objective of the Survey's study was to evalute the quantity and quality of the park's water resources. Available information was compiled and analyzed, and new data on streamflow, ground-water levels, and the chemical quality of water were collected. Test wells were drilled and aquifer tests made at the sites of wells to evaluate the occurrence and availability of ground water. (USGS)

WATER RESOURCES DATA FOR NEW HAMPSHIRE AND VERMONT, WATER YEAR 1980.
Geological Survey, Boston, MA. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-110156, Price codes: A09 in paper copy, A01 in microfiche. Geological Survey Water-Data Report NH-VT-80-1, 1981. 177 p, 3 Fig.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *New Hampshire, *Vermont.

Water-resources data for the 1980 water year for New Hampshire and Vermont consist of records of stage, discharge, and water quality of streams; stage and contents of lakes and reservoirs; and water levels and water quality of wells. This report contains discharge records for 77 gaging stations, stage records for 3 lakes, monthend contents for 25 lakes and reservoirs, water-quality data for 4 gaging stations, and water levels for 40 observation wells. Also included are data for 4 crest-stage partial-record stations. Additional water data were collected at various sites, not part of the systematic data-collection program, and are published as miscellaneous measurements. A few pertinent stations (not included above) in bordering States and Province of Quebec are also included in this report. These data represent that portion of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in New Hampshire and Vermont. (USGS)
W82-00076

WATER RESOURCES DATA FOR WEST VIRGINIA, WATER YEAR 1980.
Geological Survey, Charleston, WV. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-111637, Price codes: A21 in paper copy, A01 in microfiche. Geological Survey Water-Data Report WV-80-1, 1981. 475 p, 5 Fig.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *West Virginia.

Water resources data for the 1980 water year for West Virginia consist of records of stage, discharge, and water quality of streams and springs; stage and contents of lakes and reservoirs; and water levels in wells. This report contains discharge records for 117 gaging stations, stage only records for 8 gaging stations, stage and contents for 8 lakes and reservoirs, contents for 1 reservoir, change in contents for 1 reservoir, water quality for 101 gaging stations, and water levels for 37 observation wells. Also included are 5 crest-stage partial-record stations, and 1 low-flow partial record station. Additional water data were collected at various sites, not part of the systematic data-collection program, and are published as miscellaneous measurements and analyses. These data represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in West Virginia. (USGS)
W82-00077

WATER RESOURCES DATA FOR KANSAS, WATER YEAR 1980--VOLUME 1. MISSOURI RIVER BASIN.
Geological Survey, Lawrence, KS. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-106139, Price codes: A19 in paper copy, A01 in microfiche. Geological Survey Water-Data Report KS-80-1, 1981. 422 p, 8 Fig, 4 Tab.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *Kansas, *Missouri River basin.

Water resources data for the 1980 water year for Kansas, presented in two volumes, consist of records of stage, discharge, and water quality streams; stage, contents, and water quality of lakes and reservoirs; and water levels and water quality in wells. This volume contains discharge records for 89 gaging stations; stage and contents for 14 lakes and reservoirs; water quality for 49 gaging stations and 2 lakes; and water levels for about 176 observation wells and water quality for about 266 wells. Also included are data for 56 crest-stage partial-record stations. All data in this report represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in Kansas. (USGS)
W82-00078

WATER RESOURCES DATA FOR KANSAS, WATER YEAR 1980--VOLUME 2. ARKANSAS RIVER BASIN.
Geological Survey, Lawrence, KS. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-106147, Price codes: A16 in paper copy, A01 in microfiche. Geological Survey Water-Data Report KS-80-2, 1981. 340 p, 8 Fig, 4 Tab.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *Kansas, *Arkansas River basin.

Water resources data for the 1980 water year for Kansas, presented in two volumes, consist of records of stage, discharge, and water quality of streams; stage, contents, and water quality of lakes and reservoirs; and water levels and water quality in wells. This volume contains discharge records for 67 gaging stations; stage and contents for 7 lakes and reservoirs; water quality for 78 gaging stations; and water levels for about 306 observation wells and water quality for about 262 wells. Also included are data for 32 crest-stage partial-record stations and 22 low-flow partial-record stations. All data in this report represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in Kansas. (USGS)
W82-00079

WATER RESOURCES DATA FOR TEXAS, WATER YEAR 1979--VOLUME 1. ARKANSAS RIVER BASIN, RED RIVER BASIN, SABINE RIVER BASIN, NECHES RIVER BASIN, TRINITY RIVER BASIN, AND INTERVENING COASTAL BASINS.
Geological Survey, Austin, TX. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-110479, Price codes: $44.00 in paper copy, A01 in microfiche. Geological Survey Water-Data Report TX-79-1, 1980. 619 p, 1 Fig.

Descriptors: *Hydrologic data, *Surface water, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Data collections, Sites, *Texas, Arkansas River basin, Red River basin, Sabine River basin, Neches River basin, Trinity River basin.

Surface-water data for the 1979 water year for Texas are presented in three volumes, appropriately identified as to content by river basins. Data in each volume consist of records of stage, discharge, and water quality of streams and canals; and stage, contents, and water quality of lakes and reservoirs. Also included are crest-stage and flood-hydrograph partial-record stations, reconnaissance partial-record stations, and low-flow partial-record stations. Additional water data were collected at various sites, not part of the systematic data collection program, and are published as miscellaneous measurements. Records for a few pertinent stations in bordering States are also included. These data represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in Texas. (USGS)

W82-00082

HYDROLOGIC DATA FOR URBAN STUDIES IN THE AUSTIN, TEXAS METROPOLITAN AREA, 1979,
Geological Survey, Austin, TX. Water Resources Div.
R. M. Slade, Jr., M. E. Dorsey, J. D. Gordon, R. N. Mitchell, and J. L. Gaylord.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $36.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-628, May 1981. 281 p, 18 Fig, 17 Tab, 5 Ref.

Descriptors: *Hydrologic data, *Urban hydrology, *Urban runoff, *Rainfall-runoff relationships, *Storm runoff, Streamflow, Flow rates, Watersheds, Groundwater, Water quality, Flood profiles, Flood peak, Watershed management, Data collections, *Texas, Austin, Colorado River.

This report contains rainfall and runoff data collected during the 1979 water year for the Austin, Texas, metropolitan area. In 1975, the program was expanded to include the collection of water-quality data. In 1978, the program was expanded to include a groundwater resources study of the south Austin metropolitan area in the Balcones fault zone. The information will be useful in determining the extent to which progressive urbanization will affect the yeild and mode of occurrence of storm runoff. The major streams in the study area are the Colorado River, Onion Creek, Barton Creek, Walnut Creek, Bull Creek, Boggy Creek, Shoal Creek, Williamson Creek, Slaughter Creek, Bear Creek, and Waller Creek. Detailed rainfall-runoff computations are presented for eight storm periods during the 1979 water year. Water-quality data for sites in the Austin metropolitan area are also given in this report. (USGS)
W82-00083

PRELIMINARY DATA FROM A SERIES OF ARTIFICIAL RECHARGE EXPERIMENTS AT STANTON, TEXAS,
Geological Survey, Denver, CO. Water Resources Div.
R. L. Bassett, E. P. Weeks, M. L. Ceazan, S. G. Perkins, and D. C. Signor.
Available from the OFSS, USGS, Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $31.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-149, 1981. 235 p, 38 Fig, 84 Tab, 18 Ref.

Descriptors: *Artificial recharge, *Data collections, *Aquifers, *Hydraulic properties, Sampling, Monitoring, Tracers, Distribution, Organic compounds, Inorganic compounds, Geology, Porosity, Hydraulic conductivity, *Texas, Stanton, Ogallala Formation.

A series of artificial recharge experiments was conducted by the U.S. Geological Survey at an experimental site located in Stanton, Texas. Five tests were performed from March 1977 through December 1978 to: (1) Evaluate the hydraulic properties of the aquifer; (2) test sampling and monitoring equipment; (3) compare tracers for future use in hydrologic investigations; and (4) determine the radial and vertical distribution of hydraulic properties at the site. Suites of inorganic, and both volatile and nonvolatile organic tracers were used in the tests, and comparative data were obtained from sampling points at several radial distances and depths from the injection well. Hydraulic data from aquifer tests and geologic data from core material also were obtained during the investigation. (USGS)
W82-00085

WATER-RESOURCES INVESTIGATIONS OF THE U.S. GEOLOGICAL SURVEY IN WYOMING, FISCAL YEAR 1980,
Geological Survey, Cheyenne, WY. Water Resources Div.
S. L. Green.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $15.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-201, 1981. 118 p, 11 Fig, 5 Tab.

Descriptors: *Surface water, *Groundwater, *Water quality, *Hydrologic data, Water supply, Streamflow, Sediment transport, Reservoirs, Observation wells, Oil shale, Environmental effects, Publications, Reviews, *Wyoming, Coal regions.

This report contains lists and location maps of streamflow and reservoir stations, ground-water stations, water-quality stations, sediment stations, and peak-flow partial-record stations that are currently being operated in Wyoming. Water-resources appraisal projects are also described, including many that are related to development of energy resources. The general locations of the projects are shown on maps. The U.S. Geological Survey is striving to coordinate its water-resources investigations with those of other agencies. This report is one phase of that coordination effort and serves as an annual progress report to cooperators and the public. (USGS)
W82-00087

WATER-RESOURCES INVESTIGATIONS OF THE U.S. GEOLOGICAL SURVEY IN COLORADO--FISCAL YEAR 1981.
Geological Survey, Lakewood, CO. Water Resources Div.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $19.25 in paper copy, $4.00 in microfiche. Geological Survey Open-File Report 81-150, March 1981. 131 p, 45 Fig, 1 Plate, 1 Tab. (Compiled by William E. Price, Jr.).

Descriptors: *Surface water, *Groundwater, *Water quality, Data collections, Maps, *Colorado, Colorado River basin, Missouri River basin, Arkansas River basin, Rio Grande basin.

The report provides an overview of water-resources data collection and hydrologic investigations in Colorado from October 1, 1980, to September 30, 1981. Most of the work is carried out in cooperation with 51 Federal, State, and local agencies. Data are being collected at 503 surface-water gaging stations, 161 surface-water quality stations, and 1,151 observation wells. Sixty-seven hydrologic investigations are underway and are described in the report by a map showing the location of the study area and a statement of the purpose, objective, approach, progress, and plans. Twelve of the investigations are statewide, 6 are regional, 9 are in the Missouri River basin, 8 in the Arkansas River basin, 6 in the Rio Grande basin, and 5 are multistate. Listed in the report are references to 9 data reports and 27 interpretive reports released or published in fiscal year 1980 as a result of water-resources investigations in Colorado. (USGS)
W82-00088

GEOLOGIC, HYDROLOGIC AND CHEMICAL DATA FROM TEST WELLS IN THE DICKSON AREA, TENNESSEE,
Geological Survey, Nashville, TN. Water Resources Div.
M. W. Bradley, and J. Jonas.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $1.00 in paper copy, $0.50 in microfiche. Geological Survey Open-File Report 81-202, 1981. 1 Sheet, 3 Tab.

Descriptors: *Hydrologic data, *Groundwater, *Water quality, *Test wells, Sites, Water sampling, Well data, Well yield, Physical properties, Chemical properties, Specific capacity, Pumping tests, *Tennessee, Dickson County, Maps.

Seventeen test wells were drilled at 12 sites in south central Dickson County, Tenn. Most of the sites were selected on the basis of carefully developed concepts of groundwater occurrence. These wells range from 20 to 400 feet deep and average 276 feet deep. The yields range from 0 to 300 gal/min and average 69 gal/min, with 6 wells yielding more than 100 gal/min. The water-bearing zones in rock that yield more than 50 gal/min are all between 100 and 200 feet below land surface. Sulfur gas was detected in two of the wells and large concentrations of iron were present in other wells. Capacity tests were conducted on those wells which yield more than 100 gal/min. The specific capacities of these wells range from 1.36 to 8.11 and average 3.46 gal/min for each foot of drawdown. (USGS)

GEOGRAPHIC INFORMATION SYSTEMS AND ENVIRONMENTAL IMPACT ASSESSMENT,
Queen's Univ., Kingston (Ontario). Dept. of Geography.
C. Griffith.
Environmental Management, Vol 4, No 1, p 21-25, January, 1980. 4 Fig, 2 Tab, 5 Ref.

Descriptors: *Land use, *Environmental impact statement, *Regional analysis, Recreation, Agriculture, Canada Geographic Information System, Glengowan Dam, Thames River, Ontario, Dams, Reservoirs, Rivers, Planning, Data processing, *Canada.

The Canadian Geographic Information System categorizes land use capabilities into six groups: agriculture, forestry, recreation, wildlife, watershed boundaries, and land use. A set of seven classes in each group describes the suitability within each category for a use, Class 1 being most desirable. The data base was used to retrieve, analyze, and produce land capability statistics and land use maps for the proposed Glengowan Dam and reservoir on the Thames River, Ontario. The method, as illustrated in this paper, analyzed impacts at different levels, facilitated data profiling and assessment in areas where little information was available, and offered a spatial perspective for evaluation and communication. MODEL STUDY OF A BOX-INLET CHUTE SPILLWAY AND SAF STILLING BASIN,
Science and Education Administration, Stillwater, OK. Conservation Structures Lab.
W. R. Gwinn.
Agricultural Reviews and Manuals ARM-S-17, July 1981. 16 p, 16 Fig, 4 Tab, 4 Ref.

Descriptors: *Spillways, *Stilling basin, *Riprap, *Model studies, Flood control, *Hydraulic design, Maximum probable floods, Scour, Design flood, Stillwater Creek, Boomer Lake, Oklahoma.

Boomer Lake at Stillwater, Oklahoma, is being considered for incorporation into the flood control plan as site 23 for Stillwater Creek, to which Boomer Creek is tributary. The present concrete spillway will pass only 46% of the probable maximum flood (PMF) without overtopping the earthen embankment. A structure is being developed to contain the specified design flood. A scale model of a proposed box-inlet chute spillway and Saint Anthony Falls (SAF) stilling basin for Boomer Lake was tested to determine the head-discharge rating and required riprap. Test results indicate that the riprap should have a mean diameter of 1 foot or more and that the trapezoidal channel at the stilling basin exit should have 3:1 side slopes, with the bottom as wide as the distance between the basin sidewalls and level with the top of the end sill. The channel should be excavated to a depth equal to the maximum scour depth plus normal riprap thickness (2ft). By providing extra thickness in the area of scour, the basin will form its own natural shape if and when the extreme flows occur. (Moore-SRC)

FLOATING BREAKWATER,
Industrie Pirelli, S.p.A., Milan (Italy). (Assignee).
A. Angioletti.
U.S. Patent No. 4,234,266, 6 p, 2 Fig, 9 Ref; Official Gazette of the United States Patent Office, Vol 1000, No 3, p 1054, November 18, 1980.

Descriptors: *Patents, *Breakwaters, *Engineering structures, Barriers, Floating, Waves, Shore protection.

A floating breakwater has two closed buoyant cylindrical members spaced laterally from each other and joined together in their spaced position by longitudinally spaced flexible and inextensible strips such as rubberized fabric. Closed elongated tubular members are mounted on the cylindrical members where they will be above water. The breakwater is anchored to the bottom of the waterway by chains or the like and conventional anchors. An object of the invention is to provide a flexible floating breakwater that insures excellent protection from wave motion for an enclosed area of water and any structures on or in the water lying behind the breakwater structure. ICE PROBLEMS AT A COOLING WATER INTAKE IN A TIDAL ESTUARY AT LINGAN, N.S.,

Albery, Pullerits, Dickenson and Associates Ltd., Don Mills (Ontario).
S. Skarborn, and T. Korol.
Canadian Journal of Civil Engineering, Vol 7, No 2, p 225-232, 1980. 6 Fig, 1 Tab, 11 Ref.

Descriptors: *Cooling water, *Intakes, *Ice, Powerplants, Electric powerplants, Seawater, Estuaries, *Nova Scotia, Anchor ice, Frazil ice, Ice cover, Sea ice, Recirculated water, Canals.

Design considerations for a salt water cooling water system in a coal-fired generating station in northern Nova Scotia are described. Engineers had to study regional ice conditions; alternative sites for intakes and outfalls (near shore, medium water depth, or deep water); the bathymetry, current tides, and waves of the Bridgeport Basin channel; water temperature and salinity; local ice conditions (shorefast ice, pack ice, and frazil); channel intake design (a rubble structure extending to steel sheet pile cells which support ice booms); and the canal flow characteristics with and without ice cover. In the canal connecting the sea to the plant, water would reach the pumphouse in 15 min with no ice cover and in 13 min with ice cover at a flow rate of 25.5 cu meters per sec. Provision for recirculation of cooling water was made in case of an ice buildup at the intake. The discharged water would be let out 50 meters upstream of the pumphouse to melt some of the ice and mix thoroughly with canal water. (Cassar-FRC)

NORTHEASTERN NEW JERSEY GRAPPLES WITH A DROUGHT,
New Jersey Dept. of Environmental Protection, Trenton.
J. O'Dowd.
Public Works, Vol 112, No 6, p 74-77, June, 1981.

Descriptors: *Drought, *Reservoir operation, *Pipelines, *Pumpage, *Project planning, Water deficit, Water shortage, Water yield, Reservoirs, Water transport, Conveyance structures, Flow rates, Flow discharge, Low flow, Emergency water supply, *New Jersey.

Arrangements for temporary facilities for emergency water supply during the 1980 drought in New Jersey are described. Numerous federal and state agencies cooperated in funding and planning short and long term solutions to the water supply problem. A pipeline diverting lake water to a nearby reservoir was constructed. Water was pumped from a 100 foot deep well in New York and transported through high pressure pipes along the George Washington bridge to New Jersey. Pumping water from abandoned mines has also been explored. Additional connections to existing reservoirs are being constructed for the transfer of water. (Titus-FRC)

ENGINEERING RESEARCH AND THE WATER INDUSTRY,
Water Research Centre, Marlow (England).
M. Rouse.
Water, No 31, p 7-9, March, 1980.

Descriptors: *Water mains, *Sewers, *Research priorities, *Great Britain, Sewer systems, Water conveyance, Maintenance, Needs assessment, Engineering, Technology, Design criteria.

The Water Research Centre in Great Britain has created an Engineering Group which will concentrate its efforts on underground technology, materials, and instrumentation. Initial work by the Group will consist of developing information on sewers and water mains and conducting full scale field investigations of survey methods and pipe renovation systems. Research and development will center on increased understanding of the mechanisms leading to problems and failures and development of effective data collection systems and survey methods. The Standing Technical Committee on Sewers and Water Mains provides a forum in which Water Research Centre staff can work with the users of the research and development results. The Standing Technical Committee has conducted such activities as a study designed to measure leakage and the effectiveness of leakage control measures. Research and development efforts will attempt to focus on total problems, establishing the approach and technology needed to effectively solve existing problems. Problems which are likely to arise in the future will also be addressed. Advances in technology which may benefit water conveyance will be examined. Operational innovations will be initiated and encouraged by the Centre, but much of the innovation will be accomplished by suppliers and/or within the water industry itself. (Carroll-FRC)

DAM CONSTRUCTION IN CHINA.
International Water Power and Dam Construction, Vol 33, No 4, p 17-18, April, 1981.

Descriptors: *Peoples Republic of China, *Dam construction, *Dam design, Asia, *China, Irrigation, Earth dams, Gravity dams, Hollow dams, Arch dams.

Dam construction has been an essential tool in China's development over the past 2000 years. China has about 86,000 dams, with earthfill dams being the most common type. The use of a concrete base and a thin wall of clay inside the earthfill to provide some stiffening has proved a useful technique on river beds with thick layers of gravel subject to serious seepage. The sluicing-siltation method involves depositing loess in ponds lying higher than the crest of the dam to create a high-concentration slurry and then releasing the slurry through ditches to the construction surface of the dam embankment, where it forms a solid layer as the water drains. This method has provided an efficient, labor-saving, and relatively inexpensive means of dam construction. About 5200 irrigation networks throughout the country provide water to a total of over 46,000,000 hectares. Most of the dams are small projects, financed by rural people's communes and built between two flood seasons. Hundreds of masonry dams have been built in the country; one of these is still operating normally after 2000 years of service. While most of the masonry dams built before 1960 are of the gravity type, recent constructions have used light-type dams which incorporate a single-arch retaining wall for narrow gorges or multiple arches or hollow gravity dams on wide rivers. The giant Gezhouba dams currently being constructed on the Yangtze river in Hubei province will include two powerplants with a combined capacity of 2.7 GW, three locks (one of which will be among the largest in the world), a flood gate, and two silt gates. Many dams are now being built on China's largest rivers. (Carroll-FRC)

A NEW ERA FOR CHINA'S HYDROPOWER,
Manitoba Univ., Winnipeg. Dept. of Geography.
V. Smil.
International Water Power and Dam Construction, Vol 33, No 4, p 23-25, April, 1981. 1 Fig, 2 Tab.

Descriptors: *People's Republic of China, *Hydroelectric power, *Dam construction, Asia, *China, Planning, Dams, Electric power production, Powerplants.

Political changes in the People's Republic of China in the 1970's have ushered in an era of industrial modernization and economic development. A central focus of this effort has been the assignment of top priority to the development of hydroelectric power in the country. Bold development plans have included the proposed construction of several giant hydroelectric projects. China is also, for the first time in over 20 years, seeking foreign technical and financial assistance in designing and constructing several large planned projects. Twelve major hydroelectric plants, with total capacities of about 11 GW, are currently in various stages of construction. The largest of these is the Gezhouba on the Yangtze River, which will be 2561 meters long and 70 meters high. This dam will include two generating stations with a total capacity of 2715 MW and an annual production capacity of 13.8 TWh. The project will include three ship locks, a central sluice gate for flood control, and a dozen discharge tunnels to remove silt. Both Japan and the United States have agreed to provide loans and technical assistance for hydroelectric power development in China. (Carroll-FRC)

CHINA'S POTENTIAL FOR HYDRO DEVELOPMENT,
C. Weigong.
International Water Power and Dam Construction, Vol 33, No 4, p 18-21, April, 1981. 3 Fig, 1 Tab.

Descriptors: *People's Republic of China, *Hydroelectric power, Electric power, Planning, *China, Dam construction.

Surveys of the most important rivers in China have indicated that the total theoretical hydroelectric power potential in the People's Republic of China is 680,000 megawatts, corresponding to an annual generation of 6000 TWh of electrical energy. Although China has more water power resources than any other country, it has developed only 2.4% of the exploitable potential, with combined generating capacity of hydroelectric power installations totaling 16.02 GW. Southwest China, which includes the provinces of Sichuan, Yunnan, and Guizhou and the Tiber autonomous region, accounts for 69% of the total water power potential in the country and for about 40% of the total developed hydroelectric power. Five additional major hydropower systems currently planned for this region will serve both Southwest China and the industrial areas in East China, which are short of energy. Northwest China possesses about 12.3% of China's total hydropower resources, while Central and South China account for 9.4% of the national total. East, Northeast, and North China account for relatively negligible percentages of the total hydropower potential, and most of this has already been developed. Major planned projects in Southwest China, Northwest China, Central and South China, and East China are briefly described. (Carroll-FRC)

HYDRAULIC SEDIMENT MODEL STUDY FOR PROPOSED BLANCO DIVERSION DAM MODIFICATION,
Bureau of Reclamation, Denver, CO. Engineering and Research Center.
R. A. Dodge.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-122920, Price codes: A03 in paper copy, A01 in microfiche. Report REC-ERC-81-3, June 1981. 48 p, 42 Fig.

Descriptors: *Diversion dams, *Sediment control, *Hydraulic models, Headworks, Model studies, Trash racks, Trap efficiency, Tunnels, Suspended sediments, Hydraulic design, *Blanco Diversion Dam, *San Juan-Chama Project, Colorado, New Mexico.

Blanco Diversion Dam is the uppermost and largest of three dams on the San Juan-Chama Project. During a heavy runoff of water in 1973, operators reported large quantities of sediment passing through the headworks and tunnel. Sediment passing through the Blanco Tunnel headworks travels through about 40 km of tunnel. A 1/16-scale sediment model was used to study proposed modifications of Blanco Diversion Dam. Pit-run sand was used to simulate bed sediment sizes ranging from cobbles to fine sand, including sizes in the coarsest 7% part of suspended sediment samples. The model was verified with hydrologic estimates and field data. Tests were directed toward keeping coarse sediment out of the headworks, making sluicing of sediment less troublesome to downriver water users, reducing trash problems on the headworks rack, and keeping sediment from inter-

fering with downstream water measurement. A three-part sequential trap system in front of the headworks was developed. This system uses sluicing over successive trap walls and reduces the amount of sediment entering the tunnel to about 19% of that entering the existing system during 1971 to 1975. At lower river flows, the traps reduced the grain size of the sediment entering the tunnel to 1/20 that of the riverbed material, and at higher riverflows the reduction was to 1/5 that of the riverbed material. RESONATOR STUDIES FOR KINCARDINE HARBOUR, LAKE HURON,
McMaster Univ., Hamilton (Ontario). Dept. of Civil Engineering and Engineering Mechanics.
W. James, and D. R. Cuthbert.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 133-143, 1980. 10 Fig, 2 Tab, 8 Ref.

Descriptors: *Resonance, *Harbors, *Waves, *Kincardine Harbor, *Lake Huron, Boating, Recreation, Surveys, Acoustics, Model studies, Lakes, Breakwaters.

A series of acoustical models was used to study wave action in Kincardine Harbor, Lake Huron. Installation of sheet steel piling on the original concrete quays had produced excessive waves in the harbor, used primarily for pleasure boating. Subsequently, a resonator and rubble breakwater were constructed to exclude wave energy from the harbor. A public opinion survey of users indicated that the resonator was effective in decreasing inner harbor oscillations, but posed a navigational hazard. Conclusions were: (1) the acoustic model effectively simulated harbor resonance, (2) the existing breakwater should be extended and marked with a light, and (3) no more than two resonators of unequal lengths (60 and 80 ft) should be constructed. A utility function was proposed; it indicates an average condition of the harbor in relation to outside wave conditions. (Cassar-FRC)

8C. Hydraulic Machinery

OPTIMIZATION OF PUMP TURBINES,
Technische Univ., Munich (Germany, F.R.).
J. Raabe.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY1, p 41-63, May, 1981. 15 Fig, 29 Ref.

Descriptors: *Cost analysis, *Electric power production, *Pump turbines, *Mathematical studies, Costs, Economic aspects, Powerplants, Electric power, Turbines, Design criteria, Computer models, Model studies, Impellers.

Some costs involved with excavation work and mechanical losses which occur during the operation of pump turbines of electrical powerplants are presented. The pump turbine design should be based on an impeller outside diameter which minimizes losses from disc friction and the diffuser during pumping. This diameter may be derived mathematically as a function of the given head, flow rate, and type number. A new technique applied to calculating the type number also aids in reducing internal losses and keeps the costs of excavation to a minimum. The optimum type number is functionally related to geometrical data, cavitation coefficients, and loss. Computed results were in close agreement with values encountered in actual practice on a modern pump turbine. The pump turbine design must also take into account specific properties associated with the operation of the set. (Geiger-FRC)
W82-00181

THE CASE FOR SPECIFYING AWWA BUTTERFLY VALVES.
Water and Sewage Works, Vol 127, No 3, p 46, 51, March, 1980.

Descriptors: *Valves, *Design considerations, Equipment, Mechanical equipment, Wastewater treatment, Water treatment, Water treatment facilities, Wastewater treatment facilities, Standards, AWWA, Valves, Butterfly valves.

Basic criteria which a butterfly valve must meet to satisfy the minimum requirements of the AWWA standard are that the materials have a basic safety factor of 5:1 on the ultimate tensile strength or 3:1 on the yield strength, whichever is lower. The standard also covers the operator structure. Manual-type operators must satisfy the minimum requirements of two times the rated torque without damage to internal components. Other requirements are listed. Stringent test procedures are also contained in the AWWA standard C504; these impose significant requirements on quality and long-term cycle life for butterfly-valve applications. The clear interpretation of federal specification guidelines offers the consulting engineer the necessary freedom to specify AWWA-quality valves for EPA projects, notably municipal water and wastewater systems. (Baker-FRC)

CAVITATION AND WEAR ON HYDRAULIC MACHINES,
Chengdu Agricultural Machinery Coll. (China).
DuTong.
International Water Power and Dam Construction, Vol 33, No 4, p 26-28, 33-35, April, 1981. 6 Fig.

Descriptors: *Hydraulic machinery, *Cavitation, *Abrasion, Fluid mechanics, Hydraulic equipment, Flow friction, Sand, Maintenance, *Design criteria.

It has been widely assumed that the scaly pitting of hydraulic machinery is a typical characteristic of wear caused by the abrasion of sand contained in flowing water. Several experiments and analyses were conducted to determine whether such damage is caused by sandy water or by cavitation, including comparison of sand-washing attacks under normal atmospheric conditions and in a compressed air environment; tests with a straight tube and a cavitation generator; tests with a bent tube; tests with pumps connected in series; and tests with water passages connected in series. These tests demonstrated that when no cavitation existed, the wearing effect from the sand alone resulted in all surfaces becoming smooth, with some becoming deep brown in color while others showed a metallic lustre, regardless of the size of the sand grain. Thus elimination of cavitation will eliminate scaly pitting and other surface damage to hydraulic machinery. When sand is present in flowing water it promotes the development of bubbles, and the onset of cavitation occurs sooner than it would have in the absence of the sand. In addition, the sand will continuously wash away the protective film formed on the damaged surface by cavitation so that the sound material of the machinery is successively exposed to the action of cavitation. Sand has a direct influence on cavitation effects, intensifying deterioration and contributing to the development of long scaly pits which join to form channels along the direction of the flow stream. When hydraulic machinery will be operating in water containing a considerable amount of sand, the prevention of cavitation is one of the most important design criteria. The presence of cavitation is the essential condition for corrosion, rather than the amount of sand the water contains. (Carroll-FRC)
W82-00331

HYDRAULIC GATES: THE STATE-OF-THE-ART,
Internacional de Engenharia, Rio de Janeiro (Brazil).
P. C. Erbiste.
International Water Power and Dam Construction, Vol 33, No 4, p 43-48, April, 1981. 5 Fig, 5 Tab, 5 Ref.

Descriptors: *Hydraulic gates, *Design criteria, *Surveys, Hydraulic equipment, Gates, Hydroelectric power, Flood control, Statistical data, Design standards.

The selection of a suitable gate is one of the most important tasks of design engineers for hydraulic installations. Gate selection should be based on a complete analysis of factors which could influence performance, cost, quality, and reliability of the equipment. Past experience with successful types and local manufacturing capability should also be considered. The increasing sizes of hydroelectric power installations and flood control schemes have led to requirements for larger hydraulic gates and extensions of operating limits. Gates are also often built to the maximum allowable dimensions and heads for the gate type. The author of this article conducted a review of the state-of-the-art of hydraulic gates in 1978-1979. Summary data from this study are presented. Data are presented on the project, manufacturer, quantity, span, height, area, head, and hydrostatic load of each of the 15 largest of each type of high pressure gate, under underflow spillway gate, overflow spillway gate, and overflow and underflow spillway gate. Data are also presented on the current limits of the size and head for various types of gates. These data are intended to outline the present fields of application of gates and to assist engineers in the preliminary selection of a gate type. (Carroll-FRC)
W82-00332

8D. Soil Mechanics

PERFORMANCE OF GRANULAR SOIL COVERS ON CANALS,
Bureau of Reclamation, Denver, CO. Engineering and Research Center.
C. W. Jones.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-104696, Price codes: A04 in paper copy, A01 in microfiche. Report REC-ERC-81-7, August 1981. 70 p, 49 Fig, 1 Tab, 9 Ref, Append.

Descriptors: *Canal linings, *Erosion control, *Soil stabilization, Soil physical properties, Soil moisture, Sand, Freezing, *Seepage control, Channel erosion.

For canals that do not have concrete or other hard-surfaced, exposed-type lining, selected granular soils are often used as erosion resistant covers at the canal-water interface. Such covers are also needed on most membrane type linings provided for seepage control to hold them in place, protect them from exposure to the elements, and prevent damage to the membrane. The characteristics and observed stability of fine and coarse soil cover layers placed on 19 selected earth-lined and unlined canal reaches to resist water erosion and to protect asphalt and plastic membrane linings are reported. Soils which have generally performed well in coarse cover layers on canals with tractive forces less than 5 N/sq m have contained: maximum particle sizes between 75 and 150 mm; less than 50% passing a No. 4 sieve, and less than 10% passing a No. 200 sieve. Predominantly medium to coarse sand in the fine layer may cause the coarser layer to be unstable during canal filling and drawdown. Some cover soils placed loosely without moisture or density control will settle when water is introduced into a canal and cause cracks to form. In cold climates, freezing of soil moisture drawn to the underside of a membrane lining may cause sliding of the membrane on the subgrade during periods of thawing. (Moore-SRC)

SHEAR STRENGTH OF ROCKFILL,
Terra Tek, Salt Lake City, UT.
N. Barton, and B. Kjaernsli.
Journal of the Geotechnical Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 107, No GT7, p 873-891, July, 1981. 12 Fig, 2 Tab, 27 Ref.

Descriptors: *Rock fill, *Rockfill dams, *Strength, Rocks, Dam stability, Dam design, Leakage, Porosity.

A method was developed to estimate the peak drained friction angle of rockfill consisting of angular quarried rock, moraine, or well-rounded fluvial gravels. The peak drained friction angles of rock joints and rockfill are quantified by an equivalent roughness, an equivalent asperity or particle strength, and by the residual or friction angle. Each of these parameters can be estimated by simple index tests or by classification. The peak drained friction angle for rockfill and rock joints is inversely proportional to the log of effective normal stress. This is a positive factor in the toe region of a rockfill dam, as high values in this region can explain the high resistance to raveling during extreme leakage. Checking full-scale strength and porosity in different lifts of a dam or in a trail fill prior to dam construction may be accomplished using large-scale tilt testing of in-place compacted rockfill. (Small-FRC)

ESTIMATING END-OF-CONSTRUCTION PORE-PRESSURES IN UNSATURATED EARTH EMBANKMENTS,
Pretoria Univ. (South Africa).
G. W. Annandale.
Civil Engineer in South Africa, Vol 22, No 2, p 31-313, February, 1980. 5 Fig, 6 Ref.

Descriptors: *Pore pressure, *Embankments, Earthworks, Water pressure, Mathematical studies.

A method is presented with which the end-of-construction pore-air pressure in an embankment can be estimated. This method takes into account the degree of saturation of the soil as well as dissipation of excess pore-air pressure during construction and allows reasonable settlement and stability estimates. The distribution of end-of-construction pore-air pressure can also be studied. (Baker-FRC)

A LABORATORY MODEL FOR UNDERWATER CONSTRUCTION OF A DAM,
University of the Witwatersrand, Johannesburg (South Africa).
Z. Ofer.
Civil Engineer in South Africa, Vol 23, No 1, p 17-21, January, 1981. 8 Fig, 10 Ref.

Descriptors: *Dam construction, *Earth dams, *Rockfill dams, Dam stability, Cofferdams, Permeability, Structural models, Design criteria, Model studies.

A small-scale (270 mm high) model dam was built in the laboratory by dumping soil-stone mixtures into water. Two concepts were tested: (1) dumping of pre-mixed soil-stone mixture and (2) placement of a stone core covered with a soil layer on the upstream side. A total of 18 tests were conducted, using different combinations and types of stone and sand. A stone-dolerite soil mixture dumped in water provided a feasible solution for constructing a cofferdam in a lake. The high permeability of the mixture was reduced by placing a layer of fine impermeable material on the upstream slope. Larger proportions of stone improved stability, and larger proportions of soil decreased permeability. Use of non-plastic or very low plasticity materials was not as effective. Over a period of 15 days the permeability of the stone-dolerite dam decreased to 20% of the initial rate. This was caused by the finer particles entrapped in the spaces between the rocks. These small-scale studies may not reproduce on a full scale because of scale effects. (Cassar-FRC)

NATIONAL WATER DATA EXCHANGE (NAWDEX) SYSTEM 2000 DATA RETRIEVAL MANUAL,
Geological Survey, Reston, VA. Water Resources Div.
O. O. Williams, and W. A. Knecht.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $26.25 in paper copy, $6.50 in microfiche. Geological Survey Open-File Report 81-419, 1981. 196 p, 18 Fig, 8 Append.

Descriptors: *Data storage and retrieval, *Hydrologic data, *Training, *Information retrieval, Computer programs, *NAWDEX(National Water Data Exchange), Water Data Sources Directory, Master Water Data Index.

The manual offers general instructions on the use of SYSTEM 2000 to retrieve any type of data, and specific instructions on how to retrieve data from the U.S. Geological Survey's Water Data Sources Directory and Master Water Data Index Data Bases. The manual is divided into five major sections plus six appendixes for reference. Section I contains introductory material, including the purpose and scope of the manual, instructions on how to use the manual, basic computer concepts, and basic SYSTEM 2000 concepts. Section II contains basic instructions on retrieving and displaying data, and section III goes into more complex retrievals. Section IV explains how to make efficient use of techniques developed in sections II and III. Section V summarizes and discusses practical applications, and section IV contains all the appendixes required for reference. (USGS)

10C. Secondary Publication And Distribution

SUMMARY OF U.S. GEOLOGICAL SURVEY INVESTIGATIONS AND HYDROLOGIC CONDITIONS IN SOUTHWEST FLORIDA FOR 1979,
Geological Survey, Tallahassee, FL. Water Resources Div.
H. C. Rollins.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price: $12.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-78, 1981. 93 p, 48 Fig, 3 Tab, 7 Ref.

Descriptors: *Water management, *Publications, *Bibliographies, Groundwater, Surface water, Water quality, Streamflow, Water supply, Water use, Water resources development, Reviews, Hydrologic data, *Florida, Southwest Florida, *Geological survey projects.

This report summarizes water-resources investigations in the Southwest Florida Water Management District performed by the U.S. Geological Survey, Water Resources Division, for fiscal year 1979. The investigations are part of the Federal program of appraising the nation's water resources. The cooperative program for fiscal year 1979 included 37 interpretive investigations. Abstracts of 15 reports released during 1979 are included. The hydrologic setting of southwest Florida and discussions of surface-water, groundwater, and quality-of-water conditions are given. Hydrologic conditions in southwest Florida are described and illustrated by hydrographs of selected surface-water, groundwater, and lake-stage data-collection sites. In addition, summaries of water-use data and data on the regional observation monitor-well program are provided. (USGS)

DIRECTORY OF MEMBER ORGANIZATIONS OF THE NATIONAL WATER DATA EXCHANGE (NAWDEX),
Geological Survey, Reston, VA. Water Resources Div.
J. M. Nokes, and C. D. Blackwell.
Available from the OFSS, USGS Box 25425, Fed. Ctr., Denver, CO 80225, Price codes: $8.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-497, 1981. 59 p. (Supersedes Open-File Report 80-556).

Descriptors: *Data storage and retrieval, *Hydrologic data, *NAWDEX(National Water Data Exchange), Directories, Member organizations.

The National Water Data Exchange (NAWDEX) is a national confederation of water-oriented organizations working together to improve access to water data. It consists of member organizations from all sectors of the water-data community. This Directory provides the names, addresses, and telephone numbers of all NAWDEX member organizations and their designated NAWDEX representatives. (USGS)

Experimental Studies on the Effect of Arsenic on Microbial Degradation of Organic Matter and Algal Growth,
W82-00237 2H

EVAPOTRANSPIRATION
A Proposed Technique to Measure Evapotranspiration Using Micrometeorological Methods,
W82-00183 2D

Field Test of an Irrigation Scheduling Computer Model,
W82-00184 3F

EVOLUTION
Geomorphic and Hydraulic Evolution of Tidal Creeks on a Subsiding Beach Ridge Plain, North Inlet, S.C.,
W82-00150 2L

EXPERIMENTAL DESIGN
Sediment Trap Dynamics and Calibration: A Laboratory Evaluation,
W82-00104 7B

EXPERIMENTAL FARMS
Effect of Crop Residue on Soil Loss from Continuous Row Cropping,
W82-00145 2J

FALLOUT
Dispersal of Aspergillus Fumigatus from Sewage Sludge Compost Piles Subjected to Mechanical Agitation in Open Air,
W82-00273 5E

FATE OF POLLUTANTS
Distribution and Balance of Volatile Halogenated Hydrocarbons in the Water and Air of Covered Swimming Pools Using Chlorine for Water Disinfection,
W82-00128 5F

FATTY ACIDS
Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments. II. Features of Fatty Acids for Polluted and Unpolluted Waters,
W82-00454 5A

FAUNA
Lethality of a Suspended Clay to a Diverse Selection of Marine and Estuarine Macrofauna,
W82-00268 5C

FEDERAL JURISDICTION
Summary of the New England Conference on Legal and Institutional Incentives to Small-Scale Hydroelectric Development, January 30-31, 1979, Boston, Massachusetts.
W82-00447 6E

Water Regulations,
W82-00482 6E

FENITROTHION
Hydrolysis of Fenitrothion in Model and Natural Aquatic Systems,
W82-00157 5B

Fenitrothion Sprayed on a Pond: Kinetics of Its Distribution and Transformation in Water and Sediment,
W82-00159 5B

FENS
Vegetation and Nutrient Status of Northern Michigan Bogs and Conifer Swamps with a Comparison to Fens,
W82-00484 2I

FERTILIZERS
Coastal Bermudagrass Yield and Soil Properties as Affected by Surface-Applied Dairy Manure and Its Residue,
W82-00195 3C

Does Salt Marsh Fertilization Enhance Shellfish Production. An Application of Flow Analysis,
W82-00259 2L

The Conservative Effect of Rainfall Variation on Fertiliser Response in a Humid Environment,
W82-00316 2A

FILTERS
Concentration of Coliphages from Large Volumes of Water and Wastewater,
W82-00247 5A

Continuous Bioregeneration of Granular Activated Carbon During the Anaerobic Degradation of Catechol,
W82-00408 5D

FILTRATION
Concentration of Poliovirus in Water by Molecular Filtration,
W82-00246 5A

Upflow Water Filtration Unit, Test Results,
W82-00407 5F

Application of a Multiple Alginate Filter Method for the Determination of Water Viruses Concentration (Conception D'Une Membrane Filtrante a Base D'Alginate Pour La Concentration Des Virus Hydriques),
W82-00458 5A

FINANCING
A 201 Pollution Control Planning Tragedy,
W82-00285 6E

FISH
Relationship Between Biotransformation and the Toxicity and Fate of Xenobiotic Chemicals in Fish,
W82-00186 5C

Evaluation of Methodologies for the Determination of Acute Toxicity in Pulp and Paper Effluents,
W82-00297 5A

Clinical Tests in Aquatic Toxicology: State of the Art,
W82-00464 5A

FISH PONDS
The Harvest of Microalgae from the Effluent of a Sewage Fed High Rate Stabilization Pond by Tilapia Nilotica. Part 2: Studies of the Fish Ponds,
W82-00456 3C

The Harvest of Microalgae from the Effluent of a Sewage Fed High Rate Stabilization Pond by Tilapia Nilotica. Part 3: Maize Cultivation Experiment, Bacteriological Studies, and Economic Assessment,
W82-00457 3C

FISH POPULATIONS
The Influence of Stream Order and Selected Stream Bed Parameters on Fish Diversity in Raystown Branch, Susquehanna River Drainage, Pennsylvania,
W82-00109 2E

The Abundance of Estuarine Larval and Juvenile Fish in a South Carolina Intertidal Creek,
W82-00276 2L

Natural Variation in Abundance of Salmonid Populations in Streams and its Implications for Design of Impact Studies,
W82-00389 5C

Longitudinal Succession in Impact Assessment of River System Fish Communities,
W82-00399 5C

FISHERIES
The Valuation of Recreational Fisheries,
W82-00348 6C

FLOCCULATION
Dewatering of Industrial Clay Wastes,
W82-00041 5D

A Realistic Assessment of the Effect of Settlement on Sewage,
W82-00324 5D

Testing the Flocculation/Coagulation of Wastewater by Granulometric Analysis of Suspended Solids in the Water Using a Laser Diffraction Meter,
W82-00463 5D

FLOOD CONTROL
Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

Review of Reports for Flood Control; Westchester County Streams, New York.
W82-00103 4A

Water Resources Appraisal for Hydroelectric Licensing: Skagit River Basin, Washington.
W82-00368 6D

Water Resources Appraisal for Hydroelectric Licensing: Lewis River Basin, Washington.
W82-00370 6B

Water Resources Appraisal for Hydroelectric Licensing: Pit River Basin, California.
W82-00373 6B

FLOOD DAMAGE
Review of Reports for Flood Control; Westchester County Streams, New York.
W82-00103 4A

FLOOD DATA
Flood Data for the Sacramento River and Butte Basin 1875 to 1978, Sacramento Valley, California,
W82-00019 2E

FLOOD FORECASTING
Predicting Lake Levels by Exponential Smoothing,
W82-00118 2A

Flood Forecast and Warning System Evaluation, Susquehanna River Basin, New York, Pennsylvania and Maryland.
W82-00351 6F

FLOOD IRRIGATION
Effects of Water Regime on Growth, Yield, and Nitrogen Uptake of Rice,
W82-00330 2I

FLOOD PLAINS
Deposition of Riverborne Organic Carbon in Floodplain Wetlands and Deltas,
W82-00034 2J

FLOOD PROFILES
Flood Data for the Sacramento River and Butte Basin 1875 to 1978, Sacramento Valley, California,
W82-00019 2E

FLOOD PROTECTION
Flood Forecast and Warning System Evaluation, Susquehanna River Basin, New York, Pennsylvania and Maryland.
W82-00351 6F

FLOOD STAGES
Flood Data for the Sacramento River and Butte Basin 1875 to 1978, Sacramento Valley, California,
W82-00019 2E

FLOODING
Historical Nile Floods and Their Implications for Climatic Change,
W82-00326 2E

FLOODWATER
Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

Effect of Microcrustaceans on Blue-Green Algae in Flooded Soil,
W82-00146 6G

FLORIDA
Chemical, Physical, and Radiological Quality of Selected Public Water Supplies in Florida, February-April 1980,
W82-00010 5F

Potentiometric Surface of the Floridan Aquifer in the Suwannee River Water Management District, Florida, May 1980,

Ground Water Alternatives and Solutions,
W82-00029 6D

Supply Working Group Report.
W82-00030 6D

Conflicts and Barriers Working Group Report.
W82-00031 6E

Alternatives Working Group Report.
W82-00032 6B

Ground-Water Resources of the White River Basin, Madison County, Indiana,
W82-00412 2A

GROUNDWATER RECHARGE
Possibilities of Using Helium and Tritium Surveys for Studying Recharge Conditions of Subsurface Waters,
W82-00302 7B

GROUNDWATER RESOURCES
Ground-Water Data for Michigan, 1979,
W82-00014 2F

GROWTH
SOYROOT - A Dynamic Model of Soybean Root Growth and Water Uptake,
W82-00114 2I

The Harvest of Microalgae from the Effluent of a Sewage Fed High Rate Stabilization Pond by Tilapia Nilotica. Part 2: Studies of the Fish Ponds,
W82-00456 3C

GULLY EROSION
Gully Development in the Deep Loess Hills Region of Central Missouri,
W82-00472 2J

GYPSUM
Effects of Tillage and Gypsum Incorporation on Rain Runoff and Crust Strength in Field Soils Irrigated With Saline-Sodic Water,
W82-00327 2A

HALOGENS
Improved Water Management of Coal Conversion Processes by Preliminary Absorption of Halides,
W82-00437 5D

HARBORS
Resonator Studies for Kincardine Harbour, Lake Huron,
W82-00228 8B

HARDNESS (WATER)
Process for Removing Alkalinity and Hardness From Waters,
W82-00063 5F

HEAVY METALS
Distribution and Transport of Heavy Metals in the Sediments of a Small Northern Eutrophic Lake,
W82-00235 5B

Comparative Analysis of Sludge and Refuse Leachate: A Preliminary Report,
W82-00287 5E

Deposition of Heavy Elements on Belgian Agricultural Soils,
W82-00306 5B

Microplate Technique for Determining Accumulation of Metals by Algae,
W82-00492 5A

HERBICIDES
Photolysis of N-Nitrosodi-n-Propylamine in Water,
W82-00164 5B

Reduced Transpiration and Increased Water Efficiency by Diuron in Corn (Zea Mays),
W82-00196 2D

Picloram Dissipation in a Small Southwestern Stream,
W82-00212 5B

HISTORIC FLOODS
Flood Data for the Sacramento River and Butte Basin 1875 to 1978, Sacramento Valley, California,
W82-00019 2E

HOME-OPERATED FILTER SYSTEMS
Upflow Water Filtration Unit, Test Results,
W82-00407 5F

HUDSON RIVER
Polychlorinated Biphenyl Transport in the Hudson River, New York,
W82-00008 5B

Relationship of Water Quality of Hudson River, New York, During Peak Discharges to Geologic Characteristics of Contributing Subbasins,
W82-00009 5B

HUMIC ACIDS
Reactions of Chlorine with Selected Aromatic Models of Aquatic Humic Material,
W82-00254 5F

HYDRAULIC DESIGN
Model Study of a Box-Inlet Chute Spillway and SAF Stilling Basin,
W82-00046 8A

HYDRAULIC GATES
Hydraulic Gates: The State-of-the-Art,
W82-00332 8C

HYDRAULIC GRADIENT
Soil Hydraulic Stability in a Subsurface Drainage System,
W82-00115 2G

HYDRAULIC MACHINERY
Cavitation and Wear on Hydraulic Machines,
W82-00331 8C

HYDRAULIC MODELS
Hydraulic Sediment Model Study for Proposed Blanco Diversion Dam Modification,
W82-00446 8A

HYDRAULIC PROPERTIES
Preliminary Data From a Series of Artificial Recharge Experiments at Stanton, Texas,
W82-00085 7C

Hydraulic Properties of Coal and Related Materials, Northern Great Plains,
W82-00278 2F

HYDROCARBONS
Development of Oil-In-Water Monitor, Phase II,
W82-00100 5A

Effect of Estuarine Sediment pH and Oxidation-Reduction Potential on Microbial Hydrocarbon Degradation,
W82-00243 2L

Alkylpyridines in Surface Waters, Groundwaters, and Subsoils of a Drainage Located Adjacent to an Oil Shale Facility,
W82-00481 5B

HYDRODYNAMICS
Role of Hydrodynamic Factors in Ammonia Desorption by Diffused Aeration,
W82-00293 5D

HYDROELECTRIC PLANTS
Final Environmental Impact Statement; Dinkey Creek Project No. 2890 - California.
W82-00352 6G

Final Environmental Impact Statement; Tyee Lake Project FERC No. 3015 - Alaska.
W82-00354 6G

Final Environmental Impact Statement; South Fork American River Development, Upper Mountain Project No. 2761 - California.
W82-00367 6G

Water Resources Appraisal for Hydroelectric Licensing: Skagit River Basin, Washington.
W82-00368 6D

Water Resources Appraisal for Hydroelectric Licensing: Lewis River Basin, Washington.
W82-00370 6B

Water Resources Appraisal for Hydroelectric Licensing: Elwha River Basin, Washington.
W82-00371 6B

Water Resources Appraisal for Hydroelectric Licensing: Little Tennessee River Basin, Tennessee, North Carolina, and Georgia.
W82-00372 6B

Water Resources Appraisal for Hydroelectric Licensing: Pit River Basin, California.
W82-00373 6B

Water Resources Appraisal for Hydroelectric Licensing: Clark Fork-Pend Oreille River Basin, Montana, Idaho, Washington.
W82-00374 6B

Summary of the Midwest Conference on Small-Scale Hydropower in the Midwest: An Old Technology Whose Time Has Come.
W82-00449 6E

Legal Obstacles and Incentives to the Development of Small Scale Hydroelectric Power in Kentucky.
W82-00450 6E

HYDROELECTRIC POWER
Small-Scale Hydro in New England: 1960-1976,
W82-00169 6D

A New Era for China's Hydropower,
W82-00335 8A

China's Potential for Hydro Development,
W82-00336 8A

Summary of the New England Conference on Legal and Institutional Incentives to Small-Scale Hydroelectric Development, January 30-31, 1979, Boston, Massachusetts.
W82-00447 6E

Executive Summary, Legal Obstacles and Incentives to Small-Scale Hydroelectric Development in the Six Middle Atlantic States.
W82-00448 6E

HYDROGEN ION CONCENTRATION
Behavior of DDT, Kepone, and Permethrin in Sediment-Water Systems Under Different Oxidation-Reduction and PH Conditions,
W82-00382 5B

High pH Treatment of Combined Water Softening and Wastewater Sludges,
W82-00403 5D

HYDROGEN PEROXIDE
Biological Consequences of Treating a Lake with Hydrogen Peroxide on the Plankton Biocenosis (Biologiques Du Traitement D'Un Lac Avec Du Peroxyde D'Hydrogene Sur La Biocenose Planctonique),
W82-00305 2H

Rapid Growth Forecast for Peroxide.
W82-00345 5D

Measurements of Hydrogen Peroxide in Rainwater,
W82-00497 2K

HYDROGEN SULFIDE
Chemistry of Septicity,
W82-00325 5D

Rapid Growth Forecast for Peroxide.
W82-00345 5D

HYDROGEOLOGY
A Comparison of Nitrogen in Shallow Ground Water from Sewered and Unsewered Areas, Nassau County, New York, from 1952 Through 1976,
W82-00277 5B

An Evaluation of Sources of Nitrogen as Causes of Ground-Water Contamination in Nassau County, Long Island,
W82-00279 5B

Ground-Water Modeling: Recent Developments,
W82-00281 2F

HYDROLOGIC BUDGET
Use of River Waters That Did Not Reach the Aral Sea as a Consequence of Economic Activity During 1961-1975,
W82-00190 4A

HYDROLOGIC CYCLE
Supply Working Group Report.
W82-00030 6D

UNIV. OF ILL. URBANA-CHAMPAIGN

HYDROLOGIC DATA
Water Quality Management Studies, Lake Seminole, April-November 1978.
W82-00051 6G

Premining Hydrologic Conditions of Five Southeastern Ohio Watersheds,
W82-00054 4C

Water Resources Data for New Hampshire and Vermont, Water Year 1980.
W82-00076 7C

Water Resources Data for West Virginia, Water Year 1980.
W82-00077 7C

Water Resources Data for Kansas, Water Year 1980--Volume 1. Missouri River Basin.
W82-00078 7C

Water Resources Data for Kansas, Water Year 1980--Volume 2. Arkansas River Basin.
W82-00079 7C

Water Resources Data for Texas, Water Year 1979--Volume 1. Arkansas River Basin, Red River Basin, Sabine River Basin, Neches River Basin, Trinity River Basin, and Intervening Coastal Basins.
W82-00080 7C

Water Resources Data for Texas, Water Year 1979--Volume 2. San Jacinto River Basin, Brazos River Basin, San Bernard River Basin and Intervening Coastal Basins.
W82-00081 7C

Water Resources Data for Texas, Water Year 1979--Volume 3. Colorado River Basin, Lavaca River Basin, Guadalupe River Basin, Nueces River Basin, Rio Grande Basin, and Intervening Coastal Basin.
W82-00082 7C

Hydrologic Data for Urban Studies in the Austin, Texas Metropolitan Area, 1979,
W82-00083 7C

Quality of Water in Tibbee Creek and Tributaries Near West Point, Mississippi,
W82-00084 5B

Water-Resources Investigations of the U.S. Geological Survey in Wyoming, Fiscal Year 1980,
W82-00087 7C

Directory of Member Organizations of the National Water Data Exchange (NAWDEX),
W82-00089 10D

Geologic, Hydrologic and Chemical Data From Test Wells in the Dickson Area, Tennessee,
W82-00090 7C

Garrett County Water-Well Records, Chemical-Quality Data Ground-Water Use, Coal Test-Hole Data and Surface-Water Data.
W82-00395 2F

National Water Data Exchange (NAWDEX) System 2000 Data Retrieval Manual,
W82-00420 10B

Index to Active Hydrologic Data Collection Sites in Florida, 1980-81,

INTERTIDAL AREAS
Neap-Spring Tide Sequences of Intertidal Shoal Deposits in a Mesotidal Estuary,
W82-00112 2L

Specific Inhibition of Nitrite Oxidation by Chlorate and Its Use in Assessing Nitrification in Soils and Sediments,
W82-00242 2L

ION EXCHANGE
Process for the Removal of Inorganic Salts From a Water Stream,
W82-00055 5F

Modeling Ammonium Exchange and Regeneration on Clinoptilolite,
W82-00125 5D

IRRIGATION
January 1980 Water Levels, and Data Related to Water-level Changes, Western and South-Central Kansas,
W82-00016 2F

Water, Energy and Labor Requirements for Future Pacific Northwest Irrigation,
W82-00143 6A

IRRIGATION EFFECTS
Effect of Irrigation and Tree Density on Peach Production,
W82-00120 2I

Effects of Tillage and Gypsum Incorporation on Rain Runoff and Crust Strength in Field Soils Irrigated With Saline-Sodic Water,
W82-00327 2A

IRRIGATION EFFICIENCY
Optimal Design of Furrow Irrigation Systems,
W82-00138 3F

IRRIGATION PRACTICES
Furrow Irrigation Practices in Northern Colorado,
W82-00139 3F

IRRIGATION REQUIREMENTS
Performance of Bearing Cherry and Prune Trees Under Very Low Irrigation Rates,
W82-00119 3F

Field Test of an Irrigation Scheduling Computer Model,
W82-00184 3F

IRRIGATION-RETURN FLOW
Irrigation Tailwater Management,
W82-00392 3C

IRRIGATION SYSTEMS
Water Application Uniformity of Hose Towed Traveler Irrigators,
W82-00296 3F

IRRIGATION WATER
Irrigation Tailwater Management,
W82-00392 3C

ISOLATION
Technique for Determining Total Bacterial Virus Counts in Complex Aqueous Systems,
W82-00222 5A

ISOTOPE STUDIES
Natural Abundances of 15N as a Source Indicator for Near-Shore Marine Sedimentary and Dissolved Nitrogen,
W82-00283 5B

ISOTOPIC TRACERS
Characterisation of Domestic and Industrial Sewage in Southern California Coastal Sediments Using Nitrogen, Carbon, Sulphur, and Uranium Tracers,
W82-00147 5B

ISRAEL
Ames' Mutagenic Activity in Recycled Water from an Israeli Water Reclamation Project,
W82-00234 5D

JAPAN
Comparative Study on Organic Constituents in Polluted and Unpolluted Inland Aquatic Environments - I. Features of Hydrocarbons for Polluted and Unpolluted Waters,
W82-00453 5B

JUDICIAL DECISIONS
Legal Aspects of Subsidence Due to Well Pumping,
W82-00170 6E

JUVENILE FISH
The Abundance of Estuarine Larval and Juvenile Fish in a South Carolina Intertidal Creek,
W82-00276 2L

KANSAS
January 1980 Water Levels, and Data Related to Water-level Changes, Western and South-Central Kansas,
W82-00016 2F

Water Resources Data for Kansas, Water Year 1980--Volume 1. Missouri River Basin.
W82-00078 7C

Water Resources Data for Kansas, Water Year 1980--Volume 2. Arkansas River Basin.
W82-00079 7C

KAOLIN
Effect of Kaolin Concentration on Distribution Coefficient of Copper,
W82-00153 5B

Effect of Cations on Copper Adsorption by Kaolin,
W82-00172 2K

KAOLINITE
Lethality of a Suspended Clay to a Diverse Selection of Marine and Estuarine Macrofauna,
W82-00268 5C

KARST
Hydrochemistry of a Dolomite Karst: The Bruce Peninsula of Ontario,
W82-00321 2K

KENAI RIVER
Erosion and Sedimentation in the Kenai River, Alaska,
W82-00015 2J

KENTUCKY
Water in the Elizabethtown Area - A Study of Limestone Terrane in North-Central Kentucky,
W82-00413 5B

Legal Obstacles and Incentives to the Development of Small Scale Hydroelectric Power in Kentucky.
W82-00450 6E

KEPONE
Behavior of DDT, Kepone, and Permethrin in Sediment-Water Systems Under Different Oxidation-Reduction and PH Conditions,
W82-00382 5B

KINCARDINE HARBOR
Resonator Studies for Kincardine Harbour, Lake Huron,
W82-00228 8B

KINETICS
Fenitrothion Sprayed on a Pond: Kinetics of Its Distribution and Transformation in Water and Sediment,
W82-00159 5B

LAKE BIWA
Distribution of Obligately Oligotrophic Bacteria in Lake Biwa,
W82-00346 5A

LAKE HURON
Resonator Studies for Kincardine Harbour, Lake Huron,
W82-00228 8B

LAKE ICE
Illustration of the Roles of Snow in the Evolution of the Winter Cover of a Lake,
W82-00267 2C

LAKE MEMPHREMAGOG
The Prediction of Lacustrine Phytoplankton Diversity,
W82-00319 2H

LAKE MICHIGAN
Seasonal Particle-Size Selection by Diaptomus Sicilis in Offshore Lake Michigan,
W82-00485 2H

LAKE SEDIMENTS
Distribution and Transport of Heavy Metals in the Sediments of a Small Northern Eutrophic Lake,
W82-00235 5B

Sulfhydrolase Activity in Sediments of Wintergreen Lake, Kalamazoo County, Michigan,
W82-00241 2H

Factors Affecting Phosphorus Release from Intact Lake Sediment Cores,
W82-00251 2H

Lignocellulose Mineralization by Arctic Lake Sediments in Response to Nutrient Manipulation,
W82-00270 2H

Postdepositional Mobility of Phosphorus in Lake Sediments,
W82-00474 2H

Reduction of Sulfur Compounds in the Sediments of a Eutrophic Lake Basin,
W82-00488 2H

LAKE SEMINOLE
Water Quality Management Studies, Lake Seminole, April-November 1978.
W82-00051 6G

LAKE TAHOE
Final Environmental Impact Statement; Wastewater Treatment Facilities, South Shore Lake Tahoe Basin.
W82-00359 5D

Final Environmental Impact Statement; South Tahoe Public Utility District and Douglas County Sewer Improvement District No. 1, Appendix B: Mitigation Program.
W82-00369 6G

LAKES
Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

Predicting Lake Levels by Exponential Smoothing,
W82-00118 2A

Factors Affecting Phosphorus Release from Intact Lake Sediment Cores,
W82-00251 2H

Occurrence of Aphanomyces Ovidestruens, a Fungus Parasitic on Copepods, in Two Eutrophic Lakes,
W82-00304 2H

Prediction of Total Phosphorus Concentrations, Chlorophyll a, and Secchi Depths in Natural and Artificial Lakes,
W82-00400 2H

LAND APPLICATION
Predicting Runoff Pollutant Reduction in Buffer Zones Adjacent to Land Treatment Sites,
W82-00141 5B

The Harvest of Microalgae from the Effluent of a Sewage Fed High Rate Stabilization Pond by Tilapia Nilotica. Part 3: Maize Cultivation Experiment, Bacteriological Studies, and Economic Assessment,
W82-00457 3C

LAND DEVELOPMENT
Effect of Agricultural Land Development on Drainage Waters in the North Carolina Tidewater Region,
W82-00094 5B

LAND DISPOSAL
Electroplating Wastewater Sludge Characterization,
W82-00095 5E

Cropping Systems for Treatment and Utilization of Municipal Wastewater and Sludge,
W82-00097 5E

Nitrogen Availability from Sewage Sludge,
W82-00158 5E

Soil as a Medium for Dairy Liquid Waste Disposal,
W82-00165 5E

Leaching of Calcium and Magnesium from Soil Columns as Affected by Form of Nitrogen in Applied Sewage,
W82-00192 5E

Coastal Bermudagrass Yield and Soil Properties as Affected by Surface-Applied Dairy Manure and Its Residue,
W82-00195 3C

Enumeration of Potentially Pathogenic Bacteria from Sewage Sludges,
W82-00221 5A

Viral Transport Through Soil Columns Under Conditions of Saturated Flow,
W82-00295 5B

Final Environmental Impact Statement; Sludge Disposal and Land Reclamation in Fulton County, Illinois.
W82-00360 5E

Survival of Enteroviruses in Rapid-Infiltration Basins During the Land Application of Wastewater,
W82-00496 5D

Effects of Sewage Effluent Application on Litter Fall and Litter Decomposition in Cypress Swamps,
W82-00499 5E

LAND RECLAMATION
Land Restoration Following Oil-Well Drilling,
W82-00057 5D

Final Environmental Impact Statement; Sludge Disposal and Land Reclamation in Fulton County, Illinois.
W82-00360 5E

LAND USE
Geographic Information Systems and Environmental Impact Assessment,
W82-00338 7C

LANDFILLS
Reconnaissance of the Effect of Landfill Leachate on the Water Quality of Marshall Brook, Southwest Harbor, Hancock County, Maine,
W82-00013 5C

A Comparison of Nitrogen in Shallow Ground Water from Sewered and Unsewered Areas, Nassau County, New York, from 1952 Through 1976,
W82-00277 5B

An Evaluation of Sources of Nitrogen as Causes of Ground-Water Contamination in Nassau County, Long Island,
W82-00279 5B

Comparative Analysis of Sludge and Refuse Leachate: A Preliminary Report,
W82-00287 5E

Hydrogeologic Data for Rocky Creek Landfill and Adjacent Area, Northwest Hillsborough County, Florida, 1969-73,
W82-00417 5B

LARVAE
The Abundance of Estuarine Larval and Juvenile Fish in a South Carolina Intertidal Creek,
W82-00276 2L

LASERS
Testing the Flocculation/Coagulation of Wastewater by Granulometric Analysis of Suspended Solids in the Water Using a Laser Diffraction Meter,
W82-00463 5D

LEACHATES
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Reconnaissance of the Effect of Landfill Leachate on the Water Quality of Marshall Brook, Southwest Harbor, Hancock County, Maine,
W82-00013 5C

Lining of Waste Impoundment and Disposal Facilities.
W82-00099 5E

Leachates from Solid Waste Recovery Operations,
W82-00167 5D

Analytical Methods Evaluation for Applicability in Leachate Analysis,
W82-00380 5A

Hydrogeologic Data for Rocky Creek Landfill and Adjacent Area, Northwest Hillsborough County, Florida, 1969-73,
W82-00417 5B

LEACHING
Computer Modeling of Fluid Flow During Production and Environmental Restoration Phases of In Situ Uranium Leaching,
W82-00043 6A

Electroplating Wastewater Sludge Characterization,
W82-00095 5E

Leaching of Calcium and Magnesium from Soil Columns as Affected by Form of Nitrogen in Applied Sewage,
W82-00192 5E

LEAKAGE
Cutting the Water Losses,
W82-00310 5F

LEGAL ASPECTS
Conflicts and Barriers Working Group Report.
W82-00031 6E

Legal Aspects of Subsidence Due to Well Pumping,
W82-00170 6E

Executive Summary, Legal Obstacles and Incentives to Small-Scale Hydroelectric Development in the Six Middle Atlantic States.
W82-00448 6E

Summary of the Midwest Conference on Small-Scale Hydropower in the Midwest: An Old Technology Whose Time Has Come.
W82-00449 6E

Legal Obstacles and Incentives to the Development of Small Scale Hydroelectric Power in Kentucky.
W82-00450 6E

W82-00448 6E

LESSER SLAVE LAKE
Predicting Lake Levels by Exponential Smoothing,
W82-00118 2A

LEWIS RIVER BASIN
Water Resources Appraisal for Hydroelectric Licensing: Lewis River Basin, Washington.
W82-00370 6B

LIBRARIES
Ground-Water Information: NWWA Provides the Resources,
W82-00301 2F

LIME
Limestone-Lime Treatment of Acid Mine Drainage - Full Scale,
W82-00377 5D

Lime Stabilization and Ultimate Disposal of Municipal Wastewater Sludges,
W82-00386 5E

High pH Treatment of Combined Water Softening and Wastewater Sludges,
W82-00403 5D

LIMESTONE
Water in the Elizabethtown Area - A Study of Limestone Terrane in North-Central Kentucky,
W82-00413 5B

LIMNOLOGY
Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

Modeling Phosphorus Loading and Lake Response Under Uncertainty: A Manual and Compilation of Export Coefficients.
W82-00039 5B

LINDANE
Sorption-Desorption of Lindane by Anaerobic and Aerobic Soils,
W82-00189 5A

LINING
Lining of Waste Impoundment and Disposal Facilities.
W82-00099 5E

LIPIDS
Reduction, Methylation, and Incorporation of Arsenic into Lipids by the Marine Phytoplankton Dunaliella Tertiolecta,
W82-00239 5B

LIQUID WASTES
State-of-the-Art of Liquid Waste Disposal for Geothermal Energy Systems: 1979,
W82-00375 5E

LITERATURE REVIEW
Ground-Water Information: NWWA Provides the Resources,
W82-00301 2F

LITTER
Effects of Sewage Effluent Application on Litter Fall and Litter Decomposition in Cypress Swamps,
W82-00499 5E

LITTLE TENNESSEE RIVER BASIN
Water Resources Appraisal for Hydroelectric Licensing: Little Tennessee River Basin, Tennessee, North Carolina, and Georgia.
W82-00372 6B

LOESS
Gully Development in the Deep Loess Hills Region of Central Missouri,
W82-00472 2J

LONG ISLAND
Use of Flow-Duration Curves to Evaluate Effects of Urbanization on Streamflow Patterns on Long Island, New York,
W82-00416 4C

LONG-TERM PLANNING
WQM Five Year Strategy (FY 81-Baseline).
W82-00045 5G

MACROINVERTEBRATES
An Appraisal of Pond-Net Samples for Biological Monitoring of Lotic Macroinvertebrates,
W82-00308 7B

MADISON COUNTY
Development of a Rural Water District,
W82-00288 6A

MAGNESIUM
Leaching of Calcium and Magnesium from Soil Columns as Affected by Form of Nitrogen in Applied Sewage,
W82-00192 5E

Consecutive Amperometric Titrations for Calcium and Magnesium,
W82-00208 5A

MAINE
Reconnaissance of the Effect of Landfill Leachate on the Water Quality of Marshall Brook, Southwest Harbor, Hancock County, Maine,
W82-00013 5C

Groundwater Availability in Acadia National Park and Vicinity, Hancock and Knox Counties, Maine,
W82-00017 2F

MAINTENANCE
Cutting the Water Losses,
W82-00310 5F

MANAGEMENT PLANNING
WQM Five Year Strategy (FY 81-Baseline).
W82-00045 5G

Basin Management in the San Bernardino Basin Area,
W82-00280 6A

MANURE
Coastal Bermudagrass Yield and Soil Properties as Affected by Surface-Applied Dairy Manure and Its Residue,
W82-00195 3C

MAPS
Potentiometric Surface of the Floridan Aquifer in the Suwannee River Water Management District, Florida, May 1980,
W82-00024 7C

Potentiometric Surface of the Floridan Aquifer in the Northwest Florida Water Management District, May 1980,
W82-00025 7C

Water Resources of Prince William Forest Park, Virginia,
W82-00026 7C

Altitude of Water Table, Biscayne Aquifer, Dade County, Florida, May 1980,
W82-00409 7C

Altitude of Water Table, Biscayne Aquifer, Dade County, Florida, October 1979,
W82-00410 7C

Altitude of Water Table, Biscayne Aquifer, Dade County, Florida, March 1979,
W82-00411 7C

MARINE ANIMALS
A Salicylate-Hypochlorite Method for Determining Ammonia in Seawater,
W82-00238 5A

MARINE SEDIMENTS
Characterisation of Domestic and Industrial Sewage in Southern California Coastal Sediments Using Nitrogen, Carbon, Sulphur, and Uranium Tracers,
W82-00147 5B

Populations of Methane-Producing Bacteria and In Vitro Methanogenesis in Salt Marsh and Estuarine Sediments,
W82-00202 2L

Natural Abundances of 15N as a Source Indicator for Near-Shore Marine Sedimentary and Dissolved Nitrogen,
W82-00283 5B

MARION COUNTY LAKE
Final Environmental Impact Statement for Proposed Sewerage Facilities in the Marion County Lake Improvement District, Marion County, Kansas.
W82-00355 6G

MARSHALL BROOK
Reconnaissance of the Effect of Landfill Leachate on the Water Quality of Marshall Brook, Southwest Harbor, Hancock County, Maine,
W82-00013 5C

MARSHES
Phosphorus Dynamics of a Florida Freshwater Marsh Receiving Treated Wastewater,
W82-00108 5E

MARYLAND
Garrett County Water-Well Records, Chemical-Quality Data Ground-Water Use, Coal Test-Hole Data and Surface-Water Data.
W82-00395 2F

MASSACHUSETTS
A Model of Natural and Man-Induced Changes in Open Freshwater Wetlands on the Massachusetts Coastal Plain,
W82-00397 2I

MATHEMATICAL EQUATIONS
A Proposed Technique to Measure Evapotranspiration Using Micrometeorological Methods,
W82-00183 2D

A Comparative Study of Three Forms of the Richard Equation Used for Predicting One-Dimensional Infiltration in Unsaturated Soil,
W82-00328 2G

Rainfall Intensity-Kinetic Energy Relationships for Soil Loss Prediction,
W82-00466 2J

MATHEMATICAL MODELS
Modeling Phosphorus Loading and Lake Response Under Uncertainty: A Manual and Compilation of Export Coefficients.
W82-00039 5B

Modeling Grain Sorghum Ratoon Cropping and Associated Runoff and Sediment Losses,
W82-00113 2G

SOYROOT - A Dynamic Model of Soybean Root Growth and Water Uptake,
W82-00114 2I

LIBRARY U. OF L. URBANA-CHAMPAIGN

Transient Soil Moisture Movement Through Layered Soils Using a Finite Element Approach,
W82-00133 2G

An Infiltration Model: Development and Evaluation of Its Parameters,
W82-00137 2G

Characterisation of Domestic and Industrial Sewage in Southern California Coastal Sediments Using Nitrogen, Carbon, Sulphur, and Uranium Tracers,
W82-00147 5B

Modeling the Flux of Atmospheric Polychlorinated Biphenyls Across the Air/Water Interface,
W82-00193 5B

Management and Design Implications of a Mathematical Model of a Rapid Gravity Sand Filter Backwash,
W82-00460 5D

MATHEMATICAL STUDIES
Optimization of Pump Turbines,
W82-00181 8C

MEASUREMENT TECHNIQUES
Comparison of Automated Segmented-Flow and Discrete Analyzers for the Determination of Nutrients in Water,
W82-00483 5A

Microplate Technique for Determining Accumulation of Metals by Algae,
W82-00492 5A

MEASURING INSTRUMENTS
A Proposed Technique to Measure Evapotranspiration Using Micrometeorological Methods,
W82-00183 2D

A More Versatile Soil Water Sampler,
W82-00191 7B

BIONESS, A New Design in Multiple Net Zooplankton Samplers,
W82-00210 7B

Automation of Water Bacteriological Analysis: Running Test of an Experimental Prototype,
W82-00225 5A

MEAT PROCESSING INDUSTRY
Pilot Scales Tests on the Flotation of Abattoir Wastes by Deep U Tubes,
W82-00322 5D

MEDITERRANEAN
Environmental Resources and Restraints to Agricultural Production in a Mediterranean-Type Environment,
W82-00329 2I

MELTING
On the Estimation of Antarctic Iceberg Melt Rate,
W82-00166 2C

MEMBRANE FILTERS
Comparison of Nine Brands of Membrane Filter and the Most-Probable-Number Methods for Total Coliform Enumeration in Sewage-Contaminated Drinking Water,
W82-00203 5A

Application of a Multiple Alginate Filter Method for the Determination of Water Viruses Concentration (Conception D'Une Membrane Filtrante a Base D'Alginate Pour La Concentration Des Virus Hydriques),
W82-00458 5A

Membrane Filter Method for Enumerating Escherichia Coli,
W82-00487 5A

Impact of Verification Media and Resuscitation on Accuracy of the Membrane Filter Total Coliform Enumeration Technique,
W82-00494 5A

MERCURY
Process for Removal of Mercury and Mercury Compounds From Aqueous Solutions and Industrial Waste Liquors,
W82-00058 5D

METABOLISM
Comparison of Two Direct-Count Methods for Determining Metabolizing Bacteria in Freshwater,
W82-00495 5A

METALS
Consecutive Amperometric Titrations for Calcium and Magnesium,
W82-00208 5A

Gas Chromatographic Determination of Selenium (-II, O), -(IV), and -(VI) in Natural Waters,
W82-00257 5A

METHANE
Methane Production from Ozonated Pulp Mill Effluent,
W82-00155 5D

Anaerobic Methane Oxidation: Occurrence and Ecology,
W82-00218 2H

Comparison of In Situ and In Vitro Rates of Methane Release in Freshwater Sediments,
W82-00245 2H

Nitrogen Fixation and Methane Metabolism in a Stream Sediment-Water System Amended with Leaf Material,
W82-00486 2K

METHANE BACTERIA
Populations of Methane-Producing Bacteria and In Vitro Methanogenesis in Salt Marsh and Estuarine Sediments,
W82-00202 2L

MICHIGAN
Ground-Water Data for Michigan, 1979,
W82-00014 2F

Sulfhydrolase Activity in Sediments of Wintergreen Lake, Kalamazoo County, Michigan,
W82-00241 2H

Vegetation and Nutrient Status of Northern Michigan Bogs and Conifer Swamps with a Comparison to Fens,
W82-00484 2I

MICROBIAL DEGRADATION
Experimental Studies on the Effect of Arsenic on Microbial Degradation of Organic Matter and Algal Growth,
W82-00237 2H

Effect of Estuarine Sediment pH and Oxidation-Reduction Potential on Microbial Hydrocarbon Degradation,
W82-00243 2L

Variation in Microbial Activity in Histosols and Its Relationship to Soil Moisture,
W82-00244 2G

MIGRATION
Postdepositional Mobility of Phosphorus in Lake Sediments,
W82-00474 2H

MINE DRAINAGE
Radionuclide Concentrations in Streams in the Upper Blackfoot River Basin, Southeastern Idaho,
W82-00418 5A

MINE WASTES
Absorption of Radium and Thorium From New Mexico Uranium Mill Tailing Solutions,
W82-00040 5D

Distribution and Transport of Heavy Metals in the Sediments of a Small Northern Eutrophic Lake,
W82-00235 5B

Control Technology Strategies for Coal Preparation Waste Drainages,
W82-00440 5D

MINERAL INDUSTRY
Dewatering Florida Phosphatic Clay Wastes With Moving Screens,
W82-00049 5D

MINERALIZATION
Lignocellulose Mineralization by Arctic Lake Sediments in Response to Nutrient Manipulation,
W82-00270 2H

MINING ENGINEERING
Hydraulic Properties of Coal and Related Materials, Northern Great Plains,
W82-00278 2F

MINNESOTA
Preliminary Evaluation of Ground-Water Contamination by Coal-Tar Derivatives, St. Louis Park Area, Minnesota,
W82-00430 5B

MISSISSIPPI
Quality of Water in Tibbee Creek and Tributaries Near West Point, Mississippi,
W82-00084 5B

Facultative Lagoon Effluent Polishing Using Phase Isolation Ponds,
W82-00092 5D

Transformation of the Mouse Clonal Cell Line R846-DP8 by Mississippi River, Raw, and Finished Water Samples from Southeastern Louisiana,
W82-00215 5C

Predicted Effects on Ground Water of Construction of Divide Cut Section, Tennessee-Tombigbee Waterway, Northeastern Mississippi Using a Digital Model,
W82-00428 2F

MISSOURI
Gully Development in the Deep Loess Hills Region of Central Missouri,
W82-00472 2J

MISSOURI RIVER BASIN
Water Resources Data for Kansas, Water Year 1980--Volume 1. Missouri River Basin.
W82-00078 7C

MODEL STUDIES
Conceptual Design of a Regional Water Quality Screening Model,
W82-00038 6A

Model Study of a Box-Inlet Chute Spillway and SAF Stilling Basin,
W82-00046 8A

Water Supply and Demand in an Energy Supply Model,
W82-00050 6D

Ground-Water Modeling: Recent Developments,
W82-00281 2F

Ground-Water Resources of the White River Basin, Madison County, Indiana,
W82-00412 2A

Digital Model of the Unconsolidated Aquifer System in the Modesto Area, Stanislaus and San Joaquin Counties, California,
W82-00415 4B

Water Treatment Model for Pollutant Exposure Assessment,
W82-00500 5F

MOISTURE
Two-Dimensional Linearized Moisture Flow with Water Extraction,
W82-00405 2I

MOISTURE CONTENT
Response of Bacteria in Wastewater Sludge to Moisture Loss by Evaporation and Effect of Moisture Content on Bacterial Inactivation by Ionizing Radiation,
W82-00489 5D

Effects of Moisture Content on Long-Term Survival and Regrowth of Bacteria in Wastewater Sludge,
W82-00493 5E

MOISTURE UPTAKE
SOYROOT - A Dynamic Model of Soybean Root Growth and Water Uptake,
W82-00114 2I

MOLECULAR STRUCTURE
Pollutant Treatability: A Molecular Engineering Approach,
W82-00252 6E

MONITORING
Evaluation of Ground-Water Monitoring Network, Santa Cruz County, California,
W82-00023 7A

Basin Management in the San Bernardino Valley,
W82-00075 4B

Development of Oil-In-Water Monitor, Phase II,
W82-00100 5A

Comparison of Nine Brands of Membrane Filter and the Most-Probable-Number Methods for Total Coliform Enumeration in Sewage-Contaminated Drinking Water,
W82-00203 5A

Hydraulic Properties of Coal and Related Materials, Northern Great Plains,
W82-00278 2F

An Observation-Well Network Concept as Applied to North Carolina,
W82-00414 4B

Proposed Observation-Well Networks and Ground-Water Level Program for North Carolina,
W82-00426 4B

MONSOONS
Report on the Summer MONEX Field Phase,
W82-00265 2B

MOUNT ST. HELENS
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Mount St. Helens Volcanic-Ash Fall in the Bull Run Watershed, Oregon, March-June 1980,
W82-00002 5B

Mudflows Resulting From the May 18, 1980, Eruption of Mount St. Helens, Washington,
W82-00003 5B

Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

Effects of the Mount St. Helens Eruption on the Benthic Fauna of the Toutle River, Muddy River, and Pine Creek Drainage Basins, Washington,
W82-00005 5C

Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

Effects of Volcanism on the Glaciers of Mount St. Helens,
W82-00007 2C

MUDFLOWS
Mudflows Resulting From the May 18, 1980, Eruption of Mount St. Helens, Washington,
W82-00003 5B

Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

MULCHING
Effect of Mulch Rate on Soil Loss by Raindrop Splash,
W82-00468 2J

MUNICIPAL WASTES
Water-Related Environmental Control Requirements at Municipal Solid Waste-to-Energy Conversion Facilities,
W82-00037 5D

Comparative Analysis of Sludge and Refuse Leachate: A Preliminary Report,
W82-00287 5E

MUNICIPAL WASTEWATER
Wastewater Treatment by Rooted Aquatic Plants in Sand and Gravel Trenches,
W82-00093 5D

High-Level Ozone Disinfection of Municipal Wastewater Effluents,
W82-00379 5D

Joint Dry/Wet Weather Treatment of Municipal Wastewater at Clatskanie, Oregon,
W82-00391 5D

NASSAU COUNTY
A Comparison of Nitrogen in Shallow Ground Water from Sewered and Unsewered Areas, Nassau County, New York, from 1952 Through 1976,
W82-00277 5B

An Evaluation of Sources of Nitrogen as Causes of Ground-Water Contamination in Nassau County, Long Island,
W82-00279 5B

NATIONAL PARKS
Water Resources of Prince William Forest Park, Virginia,
W82-00026 7C

Water Resources Appraisal for Hydroelectric Licensing: Elwha River Basin, Washington.
W82-00371 6B

NATURAL WATERS
Hydrolysis of Fenitrothion in Model and Natural Aquatic Systems,
W82-00157 5B

NAWDEX (NATIONAL WATER DATA EXCHANGE)
Directory of Member Organizations of the National Water Data Exchange (NAWDEX),
W82-00089 10D

National Water Data Exchange (NAWDEX) System 2000 Data Retrieval Manual,
W82-00420 10B

NEGEV DESERT
Effects of Tillage and Gypsum Incorporation on Rain Runoff and Crust Strength in Field Soils Irrigated With Saline-Sodic Water,
W82-00327 2A

NEMATODES
Survival of Eggs and Larvae of Swine Nematode Parasites in Aerobic and Anaerobic Waste Treatment Systems,
W82-00161 5D

A 13-Month Survey of Nematodes at Three Water Treatment Plants in Southern Ontario, Canada,
W82-00294 5F

NETHERLANDS
Neap-Spring Tide Sequences of Intertidal Shoal Deposits in a Mesotidal Estuary,
W82-00112 2L

NETWORK DESIGN
Evaluation of Ground-Water Monitoring Network, Santa Cruz County, California,
W82-00023 7A

Mathematical Efficiency Concerns in Water Distribution Network Considerations,
W82-00339 5F

Proposed Observation-Well Networks and Ground-Water Level Program for North Carolina,
W82-00426 4B

NETWORKS
An Observation-Well Network Concept as Applied to North Carolina,
W82-00414 4B

NEUTRALIZATION
Limestone-Lime Treatment of Acid Mine Drainage - Full Scale,
W82-00377 5D

NEW ENGLAND
Small-Scale Hydro in New England: 1960-1976,
W82-00169 6D

Summary of the New England Conference on Legal and Institutional Incentives to Small-Scale Hydroelectric Development, January 30-31, 1979, Boston, Massachusetts.
W82-00447 6E

NEW ENGLAND RIVER BASINS COMMISSION
Before the Well Runs Dry: A Handbook for Designing a Local Water Conservation Plan.
W82-00396 3D

NEW HAMPSHIRE
Water Resources Data for New Hampshire and Vermont, Water Year 1980.
W82-00076 7C

NEW JERSEY
Northeastern New Jersey Grapples With a Drought,
W82-00289 8A

NEW MEXICO
Evaluation of the Malaga Bend Salinity Alleviation Project, Eddy County, New Mexico,
W82-00018 5B

NEW SOUTH WALES
Solar Cycles and Erosional Events on the New South Wales Central and South Coasts,
W82-00318 2J

NEW YORK
Polychlorinated Biphenyl Transport in the Hudson River, New York,
W82-00008 5B

Relationship of Water Quality of Hudson River, New York, During Peak Discharges to Geologic Characteristics of Contributing Subbasins,
W82-00009 5B

Water Resources Investigations in New York--1980.
W82-00011 7C

Use of Flow-Duration Curves to Evaluate Effects of Urbanization on Streamflow Patterns on Long Island, New York,
W82-00416 4C

NEW YORK BIGHT
An Analysis of Factors Affecting Oxygen Depletion in the New York Bight,
W82-00106 5C

NEW ZEALAND
Occurrence of Aphanomyces Ovidestruens, a Fungus Parasitic on Copepods, in Two Eutrophic Lakes,
W82-00304 2H

NILE FLOODS
Historical Nile Floods and Their Implications for Climatic Change,
W82-00326 2E

NITRIFICATION
Specific Inhibition of Nitrite Oxidation by Chlorate and Its Use in Assessing Nitrification in Soils and Sediments,
W82-00242 2L

NITROGEN
Nitrogen Availability from Sewage Sludge,
W82-00158 5E

Effects of Soil Water Regime and Nitrogen Form on Blossom-End Rot, Yield, Water Relations, and Elemental Composition of Tomato,
W82-00162 2I

Amounts and Relative Significance of Runoff Types in the Transport of Nitrogen into a Stream Draining an Agricultural Watershed,
W82-00173 5B

A Comparison of Nitrogen in Shallow Ground Water from Sewered and Unsewered Areas, Nassau County, New York, from 1952 Through 1976,
W82-00277 5B

An Evaluation of Sources of Nitrogen as Causes of Ground-Water Contamination in Nassau County, Long Island,
W82-00279 5B

Natural Abundances of 15N as a Source Indicator for Near-Shore Marine Sedimentary and Dissolved Nitrogen,
W82-00283 5B

The Importance of Regenerated Nitrogen to Phytoplankton Productivity in a Subalpine Lake,
W82-00476 2H

NITROGEN COMPOUNDS
Does Salt Marsh Fertilization Enhance Shellfish Production. An Application of Flow Analysis,
W82-00259 2L

NITROGEN FIXATION
Nitrogen Fixation and the Nitrogen Budget of a Eutrophic Impoundment,
W82-00127 2H

Effect of Microcrustaceans on Blue-Green Algae in Flooded Soil,
W82-00146 6G

Enumeration and Relative Importance of Acetylene-Reducing (Nitrogen-Fixing) Bacteria in a Delaware Salt Marsh,
W82-00248 2L

Nitrogen Fixation and Methane Metabolism in a Stream Sediment-Water System Amended with Leaf Material,
W82-00486 2K

NITROGEN REMOVAL
Luxury Uptake of Nitrogen in Flocculating Algal-Bacterial System,
W82-00307 5D

NITROSAMINES
Photolysis of N-Nitrosodi-n-Propylamine in Water,
W82-00164 5B

Nitrosamines in Tap Water After Concentration by a Carbonaceous Adsorbent,
W82-00459 5A

NONPOINT POLLUTION SOURCES
Predicting Runoff Pollutant Reduction in Buffer Zones Adjacent to Land Treatment Sites,
W82-00141 5B

Pollution From Land Runoff,
W82-00253 5B

Natural Variation in Abundance of Salmonid Populations in Streams and its Implications for Design of Impact Studies,
W82-00389 5C

NORTH CAROLINA
Effect of Agricultural Land Development on Drainage Waters in the North Carolina Tidewater Region,
W82-00094 5B

An Observation-Well Network Concept as Applied to North Carolina,
W82-00414 4B

Proposed Observation-Well Networks and Ground-Water Level Program for North Carolina,
W82-00426 4B

NORTH INLET ESTUARY
The Abundance of Estuarine Larval and Juvenile Fish in a South Carolina Intertidal Creek,
W82-00276 2L

NORTHWEST HILLSBOROUGH COUNTY
A 201 Pollution Control Planning Tragedy,
W82-00285 6E

NOVA SCOTIA
Impact of Construction of a Hydroelectric Project on the Water Quality of Five Lakes in Nova Scotia,
W82-00227 5C

Ice Problems at a Cooling Water Intake in a Tidal Estuary at Lingan, N.S.,
W82-00230 8A

NUCLEAR REACTORS
Field Experiments on Responses of a Freshwater, Benthic Macroinvertebrate Community to Vertebrate Predators,
W82-00477 5C

NUTRIENTS
Slash Treatment After Clearcutting Lodgepole Pine Affects Nutrients in Soil Water,
W82-00130 4C

An Empirical Equation for Predicting Soluble Phosphorus Loads from Agricultural Watersheds,
W82-00134 5B

Sediment and Nutrient Movement from the Black Creek Watershed,
W82-00135 5B

Modeling the Relationship Between Development and Storm Water and Nutrient Runoff,
W82-00260 2A

Lignocellulose Mineralization by Arctic Lake Sediments in Response to Nutrient Manipulation,
W82-00270 2H

Comparison of Automated Segmented-Flow and Discrete Analyzers for the Determination of Nutrients in Water,
W82-00483 5A

Vegetation and Nutrient Status of Northern Michigan Bogs and Conifer Swamps with a Comparison to Fens,
W82-00484 2I

OAK RIDGE NATIONAL LABORATORY
Water Level Data for Wells in and Near Burial Ground 3, Oak Ridge National Laboratory, Tennessee, 1975-1979,
W82-00423 7C

OBSERVATION WELLS
January 1980 Water Levels, and Data Related to Water-level Changes, Western and South-Central Kansas,
W82-00016 2F

An Observation-Well Network Concept as Applied to North Carolina,
W82-00414 4B

Water Level Data for Wells in and Near Burial Ground 3, Oak Ridge National Laboratory, Tennessee, 1975-1979,
W82-00423 7C

Hydrogeologic Data from Test Drilling near Verna Beach, Florida, 1978,
W82-00424 2F

Proposed Observation-Well Networks and Ground-Water Level Program for North Carolina,
W82-00426 4B

ODOR CONTROL
Odorous Compounds from Potato Processing Waste Effluent Irrigation Fields: Volatile Acids,
W82-00156 5E

ODORS
Chemistry of Septicity,
W82-00325 5D

OFF-ROAD VEHICLE EFFECTS
Physical Effects of Vehicular Disturbances on Arid Landscapes,
W82-00111 4C

OGALLALA FORMATION
Water-Level Records for the Northern High Plains of Colorado, 1977-81,
W82-00422 7C

OHIO
Premining Hydrologic Conditions of Five Southeastern Ohio Watersheds,
W82-00054 4C

OIL FIELDS
Land Restoration Following Oil-Well Drilling,
W82-00057 5D

OIL INDUSTRY
Evaluation of the Effectiveness of Granular Activated Carbon Adsorption and Aquaculture for Removing Toxic Compounds From Treated Petroleum Refinery Effluents,
W82-00098 5D

Deep Well Injection of Industrial Wastes,
W82-00475 5E

OIL POLLUTION
Method and Apparatus for Pollutant Spill Control,
W82-00056 5G

Means and Method for Sweeping Material Floating on Water Using Vibrational Energy, W82-00062 5G

Development of Oil-In-Water Monitor, Phase II, W82-00100 5A

OIL SHALE
The Analysis of Oil Shale Wastes: A Review, W82-00388 5A

Assessment of Oil Shale Retort Wastewater Treatment and Control Technology - Phases I and II, W82-00390 5B

Processing Needs and Methodology for Wastewaters from the Conversion of Coal, Oil Shale and Biomass to Synfuels. W82-00431 5D

Environmental Control Technology for Shale Oil Wastewaters, W82-00444 5D

Potential Uses of Spent Shale in the Treatment of Oil Shale Retort Waters, W82-00445 5D

Alkylpyridines in Surface Waters, Groundwaters, and Subsoils of a Drainage Located Adjacent to an Oil Shale Facility, W82-00481 5B

OIL SPILLS
Method and Apparatus for Pollutant Spill Control, W82-00056 5G

Means and Method for Sweeping Material Floating on Water Using Vibrational Energy, W82-00062 5G

OILY WATER
Apparatus for the Purification of Oily Emulsions, Solutions, and Industrial Waste Waters, W82-00060 5D

Development of Oil-In-Water Monitor, Phase II, W82-00100 5A

OKLAHOMA
Report of the Annual Yield of the Arkansas River Basin for the Arkansas River Basin Compact, Arkansas--Oklahoma, 1980 Water Year, W82-00012 6E

OLATHE
Final Environmental Impact Statement for Wastewater Treatment Facilities; City of Olathe, Johnson County, Kansas. W82-00357 5D

OLIGOTROPHY
Distribution of Obligately Oligotrophic Bacteria in Lake Biwa, W82-00346 5A

ON-SITE DATA COLLECTIONS
Hydrogeologic Data from Test Drilling near Verna Beach, Florida, 1978, W82-00424 2F

ONTARIO
Geochemistry of a Subarctic Salt Marsh Environment, W82-00148 2L

Recent Developments in Water Pollution Control, W82-00340 5D

OPEN CHANNEL FLOW
Secondary Flow, Shear Stress and Sediment Transport, W82-00117 2J

OPTIMIZATION
Optimal Design of Furrow Irrigation Systems, W82-00138 3F

RURAL AREAS
Bacterial Contamination of Drinking Water Supplies in a Modern Rural Neighborhood,
W82-00198 5A

Staphylococcus Aureus in Rural Drinking Water,
W82-00223 5B

Hygiene of Drinking Water in Developing Countries,
W82-00269 5F

Development of a Rural Water District,
W82-00288 6A

Upflow Water Filtration Unit, Test Results,
W82-00407 5F

SACRAMENTO RIVER
Flood Data for the Sacramento River and Butte Basin 1875 to 1978, Sacramento Valley, California,
W82-00019 2E

SALINE WATER
Effects of Tillage and Gypsum Incorporation on Rain Runoff and Crust Strength in Field Soils Irrigated With Saline-Sodic Water,
W82-00327 2A

SALINITY
Evaluation of the Malaga Bend Salinity Alleviation Project, Eddy County, New Mexico,
W82-00018 5B

Sodium-Potassium Ratios in Soil Solution and Plant Response Under Saline Conditions,
W82-00469 3C

SALMON
Natural Variation in Abundance of Salmonid Populations in Streams and its Implications for Design of Impact Studies,
W82-00389 5C

SALT MARSHES
Geochemistry of a Subarctic Salt Marsh Environment,
W82-00148 2L

Enrichment and Association of Bacteria and Particulates in Salt Marsh Surface Water,
W82-00201 2L

Populations of Methane-Producing Bacteria and In Vitro Methanogenesis in Salt Marsh and Estuarine Sediments,
W82-00202 2L

Enumeration and Relative Importance of Acetylene-Reducing (Nitrogen-Fixing) Bacteria in a Delaware Salt Marsh,
W82-00248 2L

SALTS
Areal Predictions of Water and Solute Flux in the Unsaturated Zone,
W82-00381 6A

SAMPLE PRESERVATION
Redox Stability of Inorganic Arsenic(III) and Arsenic(V) in Aqueous Solution,
W82-00206 5A

SAMPLING
A More Versatile Soil Water Sampler,
W82-00191 7B

Graphical Effluent Quality Control for Compliance Monitoring: What Is a Violation,
W82-00261 5G

An Appraisal of Pond-Net Samples for Biological Monitoring of Lotic Macroinvertebrates,
W82-00308 7B

Understanding Acid Rain,
W82-00479 5B

SAN BERNARDINO VALLEY
Basin Management in the San Bernardino Valley,
W82-00075 4B

Basin Management in the San Bernardino Basin Area,
W82-00280 6A

SAN JUAN-CHAMA PROJECT
Hydraulic Sediment Model Study for Proposed Blanco Diversion Dam Modification,
W82-00446 8A

SAN PEDRO
Characterisation of Domestic and Industrial Sewage in Southern California Coastal Sediments Using Nitrogen, Carbon, Sulphur, and Uranium Tracers,
W82-00147 5B

SANTA BARBARA BASIN
Natural Abundances of 15N as a Source Indicator for Near-Shore Marine Sedimentary and Dissolved Nitrogen,
W82-00283 5B

SANTA CRUZ COUNTY
Evaluation of Ground-Water Monitoring Network, Santa Cruz County, California,
W82-00023 7A

SATELLITE TECHNOLOGY
SEASAT SAR Response from Water Resources Parameters,
W82-00101 7B

SCOTLAND
The Effect of Centrifugation on the Suspended Particles of River Waters,
W82-00124 5A

SEAWATER
A Salicylate-Hypochlorite Method for Determining Ammonia in Seawater,
W82-00238 5A

Water-Rock Partition Coefficients and the Composition of Natural Waters - A Reassessment,
W82-00284 2K

SECONDARY PRODUCTIVITY
Methane Production from Ozonated Pulp Mill Effluent,
W82-00155 5D

SECONDARY WASTEWATER
Phosphorus Dynamics of a Florida Freshwater Marsh Receiving Treated Wastewater,
W82-00108 5E

SECONDARY WASTEWATER TREATMENT
Final Environmental Impact Statement, City of Portage Wastewater System, Columbia County, Wisconsin.
W82-00356 6G

SEDIMENT CONTROL
Hydraulic Sediment Model Study for Proposed Blanco Diversion Dam Modification,
W82-00446 8A

SEDIMENT DEPOSITION
Neap-Spring Tide Sequences of Intertidal Shoal Deposits in a Mesotidal Estuary,
W82-00112 2L

SEDIMENT DISTRIBUTION
Deposition of Riverborne Organic Carbon in Floodplain Wetlands and Deltas,
W82-00034 2J

SEDIMENT TRANSPORT
Relationship of Water Quality of Hudson River, New York, During Peak Discharges to Geologic Characteristics of Contributing Subbasins,
W82-00009 5B

Secondary Flow, Shear Stress and Sediment Transport,
W82-00117 2J

Sediment and Nutrient Movement from the Black Creek Watershed,
W82-00135 5B

Sediment Transport in Norton Sound, Alaska,
W82-00151 2J

SEDIMENTATION
Erosion and Sedimentation in the Kenai River, Alaska,
W82-00015 2J

SEDIMENTS
Water Quality Management Studies, Lake Seminole, April-November 1978.
W82-00051 6G

Sediment Trap Dynamics and Calibration: A Laboratory Evaluation,
W82-00104 7B

Field Assessment of Sediment Traps,
W82-00105 7B

Sorption of Trace Cadmium on Clay Minerals and River Sediments: Effects of pH AND CD(II) Concentrations in a Synthetic River Water Medium,
W82-00174 2K

Influence of Estuarine Sediment on Virus Survival Under Field Conditions,
W82-00199 5A

Anaerobic Methane Oxidation: Occurrence and Ecology,
W82-00218 2H

Effect of Estuarine Sediment pH and Oxidation-Reduction Potential on Microbial Hydrocarbon Degradation,
W82-00243 2L

Comparison of In Situ and In Vitro Rates of Methane Release in Freshwater Sediments,
W82-00245 2H

Factors Affecting Phosphorus Release from Intact Lake Sediment Cores,
W82-00251 2H

Thermostabilization of Enteroviruses by Estuarine Sediment,
W82-00263 2L

Development of Bioassay Procedures for Defining Pollution of Harbor Sediments,
W82-00387 5C

Nitrogen Fixation and Methane Metabolism in a Stream Sediment-Water System Amended with Leaf Material,
W82-00486 2K

SEEPAGE CONTROL
Performance of Granular Soil Covers on Canals,
W82-00047 8D

SELENIUM
Gas Chromatographic Determination of Selenium (-II, O), -(IV), and -(VI) in Natural Waters,
W82-00257 5A

SEPARATION TECHNIQUES
Land Restoration Following Oil-Well Drilling,
W82-00057 5D

Process for Removal of Mercury and Mercury Compounds From Aqueous Solutions and Industrial Waste Liquors,
W82-00058 5D

Apparatus for the Purification of Oily Emulsions, Solutions, and Industrial Waste Waters,
W82-00060 5D

High Capacity Waste Water Treatment System,
W82-00066 5D

Removal and Recovery of Organic Pollutants from the Aquatic Enviroment. 2. Removal and Recovery of Dodecylbenzenesulfonate from Aqueous Solution by Cross-Linked Poly(N-Benzyl-4-Vinylpyridinium Halide),
W82-00217 5D

SEPTICITY
Chemistry of Septicity,
W82-00325 5D

SETTLEABLE SOLIDS
The Operation of a Waste Treatment Plant. Process Dynamic Considerations,
W82-00298 5D

SEWAGE BACTERIA
Incidence of Vibrio Alginolyticus and Bacteria of Sanitary Significance in the Bering Sea,
W82-00490 5A

Effect of Solar Radiation and Predacious Microorganisms on Survival of Fecal and Other Bacteria,
W82-00491 2L

SEWAGE TREATMENT
High Capacity Waste Water Treatment System,
W82-00066 5D

SEWER SYSTEMS
Final Environmental Impact Statement for Proposed Sewerage Facilities in the Marion County Lake Improvement District, Marion County, Kansas.
W82-00355 6G

Final Environmental Impact Statement for Wastewater Treatment Facilities; City of Olathe, Johnson County, Kansas.
W82-00357 5D

Final Environmental Impact Statement; Alternative Wastewater Treatment Systems for Rural Lake Projects; Case Study No. 2: The Green Lake Sanitary Sewer and Waste District, Kandiyohi County, Minnesota.
W82-00363 5D

Final Environmental Impact Statement; Alternative Wastewater Treatment Systems for Rural Lake Projects; Case Study No. 4: Steuben Lakes Regional Waste District, Steuben County, Indiana.
W82-00365 5D

Final Environmental Impact Statement; Alternative Wastewater Treatment Systems for Rural Lake Projects; Case Study No. 5: Otter Tail County Board of Commissioners, Otter Tail County, Minnesota.
W82-00366 5D

SEWERS
Engineering Research and the Water Industry,
W82-00313 8A

SHEAR STRESS
Secondary Flow, Shear Stress and Sediment Transport,
W82-00117 2J

SHELLFISH
An Analysis of Factors Affecting Oxygen Depletion in the New York Bight,
W82-00106 5C

Improved Method and Test Strategy for Recovery of Enteric Viruses from Shellfish,
W82-00219 5A

Does Salt Marsh Fertilization Enhance Shellfish Production. An Application of Flow Analysis,
W82-00259 2L

SHORE PROTECTION
The Significance of the Submarine Geology of Upper Spencer Gulf, South Australia, to Environmental Decision-Making,
W82-00314 2L

SILICATES
Silicates as Nonspecific Adsorbents of Bacteriophage: A Model for Purification of Water From Viruses,
W82-00350 5F

SINKS
Two-Dimensional Linearized Moisture Flow with Water Extraction,
W82-00405 2I

SITES
Index to Active Hydrologic Data Collection Sites in Florida, 1980-81,
W82-00425 7C

SKAGIT RIVER BASIN
Water Resources Appraisal for Hydroelectric Licensing: Skagit River Basin, Washington.
W82-00368 6D

SLATE BELT
The Effects of Surface Slaty Fragments on Soil Erosion by Water,
W82-00471 2J

SLUDGE
Electroplating Wastewater Sludge Characterization,
W82-00095 5E

Nitrogen Availability from Sewage Sludge,
W82-00158 5E

Enumeration of Potentially Pathogenic Bacteria from Sewage Sludges,
W82-00221 5A

Recovery of Indigenous Viruses from Wastewater Sludges, Using a Bentonite Concentration Procedure,
W82-00271 5D

Dispersal of Aspergillus Fumigatus from Sewage Sludge Compost Piles Subjected to Mechanical Agitation in Open Air,
W82-00273 5E

Response of Bacteria in Wastewater Sludge to Moisture Loss by Evaporation and Effect of Moisture Content on Bacterial Inactivation by Ionizing Radiation,
W82-00489 5D

Effects of Moisture Content on Long-Term Survival and Regrowth of Bacteria in Wastewater Sludge,
W82-00493 5E

SLUDGE CONDITIONING
Sludge Settling Hampered by Industrial Discharge,
W82-00290 5D

Lime Stabilization and Ultimate Disposal of Municipal Wastewater Sludges,
W82-00386 5E

SLUDGE DIGESTION
Sludge Settling Hampered by Industrial Discharge,
W82-00290 5D

SLUDGE DISPOSAL
Cropping Systems for Treatment and Utilization of Municipal Wastewater and Sludge,
W82-00097 5E

Comparative Analysis of Sludge and Refuse Leachate: A Preliminary Report,
W82-00287 5E

Final Environmental Impact Statement; Sludge Disposal and Land Reclamation in Fulton County, Illinois.
W82-00360 5E

Engineering Assessment of Vermicomposting Municipal Wastewater Sludges,
W82-00385 5E

Lime Stabilization and Ultimate Disposal of Municipal Wastewater Sludges,
W82-00386 5E

SLUDGE DRYING
Effects of Moisture Content on Long-Term Survival and Regrowth of Bacteria in Wastewater Sludge,
W82-00493 5E

SLURRIES
Water Pollution Potential of Coal-Slurry Pipelines,
W82-00096 6A

SLUSH
Illustration of the Roles of Snow in the Evolution of the Winter Cover of a Lake,
W82-00267 2C

SNOW
Effects of Volcanism on the Glaciers of Mount St. Helens,
W82-00007 2C

SNOW COVER
Illustration of the Roles of Snow in the Evolution of the Winter Cover of a Lake,
W82-00267 2C

SNOW MANAGEMENT
Economics of Snow Management for Agriculture in the Great Plains,
W82-00178 3F

SNOWMELT
Economics of Snow Management for Agriculture in the Great Plains,
W82-00178 3F

SOCIAL ASPECTS
Report of Survey of Corps of Engineers Construction Workforce,
W82-00102 6B

SODIUM
Sodium-Potassium Ratios in Soil Solution and Plant Response Under Saline Conditions,
W82-00469 3C

SOIL COLUMNS
Leaching of Calcium and Magnesium from Soil Columns as Affected by Form of Nitrogen in Applied Sewage,
W82-00192 5E

SOIL COMPACTION
Unsaturated Water Flow Through a Simulated Wheel Track,
W82-00473 2G

SOIL CONSERVATION
Protecting Agriculture's Natural Resource Base,
W82-00176 4D

SOIL CONTAMINATION
Deposition of Heavy Elements on Belgian Agricultural Soils,
W82-00306 5B

SOIL EROSION
Physical Effects of Vehicular Disturbances on Arid Landscapes,
W82-00111 4C

Erodibility of Streambank Materials of Low Cohesion,
W82-00136 2J

Effect of Crop Residue on Soil Loss from Continuous Row Cropping,
W82-00145 2J

Rainfall Intensity-Kinetic Energy Relationships for Soil Loss Prediction,
W82-00466 2J

Effect of Mulch Rate on Soil Loss by Raindrop Splash,
W82-00468 2J

Effects of Small Amounts of Residue on Furrow Erosion,
W82-00470 2J

The Effects of Surface Slaty Fragments on Soil Erosion by Water,
W82-00471 2J

SOIL MANAGEMENT
Estimating the Physical Carrying Capacity of Recreation Areas: A Rationale for Application of the Universal Soil Loss Equation,
W82-00274 2J

SOIL MOISTURE
Variation in Microbial Activity in Histosols and Its Relationship to Soil Moisture,
W82-00244 2G

SOIL PHYSICAL PROPERTIES
Unsaturated Water Flow Through a Simulated Wheel Track,
W82-00473 2G

SOIL PROFILES
Effects of Topsoil and Subsoil Thickness on Soil Water Content and Crop Production on a Disturbed Soil,
W82-00465 2G

SOIL PROPERTIES
The Effects of Surface Slaty Fragments on Soil Erosion by Water,
W82-00471 2J

SOIL SATURATION
Soil Hydraulic Stability in a Subsurface Drainage System,
W82-00115 2G

SOIL STABILITY
Soil Hydraulic Stability in a Subsurface Drainage System,
W82-00115 2G

SOIL STABILIZATION
Performance of Granular Soil Covers on Canals,
W82-00047 8D

SOIL STRENGTH
Effects of Tillage and Gypsum Incorporation on Rain Runoff and Crust Strength in Field Soils Irrigated With Saline-Sodic Water,
W82-00327 2A

SOIL TYPES
Viral Transport Through Soil Columns Under Conditions of Saturated Flow,
W82-00295 5B

SOIL WATER
SEASAT SAR Response from Water Resources Parameters,
W82-00101 7B

Transient Soil Moisture Movement Through Layered Soils Using a Finite Element Approach,
W82-00133 2G

An Infiltration Model: Development and Evaluation of Its Parameters,
W82-00137 2G

A More Versatile Soil Water Sampler,
W82-00191 7B

A Comparative Study of Three Forms of the Richard Equation Used for Predicting One-Dimensional Infiltration in Unsaturated Soil,
W82-00328 2G

Environmental Resources and Restraints to Agricultural Production in a Mediterranean-Type Environment,
W82-00329 2I

Areal Predictions of Water and Solute Flux in the Unsaturated Zone,
W82-00381 6A

Effects of Topsoil and Subsoil Thickness on Soil Water Content and Crop Production on a Disturbed Soil,
W82-00465 2G

SOIL WATER MOVEMENT
Transient Soil Moisture Movement Through Layered Soils Using a Finite Element Approach,
W82-00133 2G

SOIL-WATER-PLANT RELATIONSHIPS
Effects of Soil Water Regime and Nitrogen Form on Blossom-End Rot, Yield, Water Relations, and Elemental Composition of Tomato,
W82-00162 2I

SOLAR RADIATION
Effect of Solar Radiation and Predacious Microorganisms on Survival of Fecal and Other Bacteria,
W82-00491 2L

SOLUBILITY
Measurement of the Solubilities of Slightly Soluble Organic Liquids in Water by Elution Chromatography,
W82-00207 5A

SOLVENTS
Determination of Trace Quantities of Dimethylsulfoxide in Aqueous Solutions,
W82-00205 5A

SORGHUM
Modeling Grain Sorghum Ratoon Cropping and Associated Runoff and Sediment Losses,
W82-00113 2G

SORPTION
Sorption of Trace Cadmium on Clay Minerals and River Sediments: Effects of pH AND CD(II) Concentrations in a Synthetic River Water Medium,
W82-00174 2K

Sorption-Desorption of Lindane by Anaerobic and Aerobic Soils,
W82-00189 5A

SOUNDS
Sediment Transport in Norton Sound, Alaska,
W82-00151 2J

SOUTH AFRICA
Nitrogen Fixation and the Nitrogen Budget of a Eutrophic Impoundment,
W82-00127 2H

Field Test of an Irrigation Scheduling Computer Model,
W82-00184 3F

Environmental Planning for Coal Strip Mining,
W82-00214 5G

SOUTH CAROLINA
Element Mass Balances for South Carolina Coastal Plain Watersheds,
W82-00175 5B

The Abundance of Estuarine Larval and Juvenile Fish in a South Carolina Intertidal Creek,
W82-00276 2L

SOUTH FORK AMERICAN RIVER PROJECT
Final Environmental Impact Statement; South Fork American River Development, Upper Mountain Project No. 2761 - California.
W82-00367 6G

SOUTHERN PIEDMONT
The Effects of Surface Slaty Fragments on Soil Erosion by Water,
W82-00471 2J

SOYBEANS
SOYROOT - A Dynamic Model of Soybean Root Growth and Water Uptake,
W82-00114 2I

SPATIAL DISTRIBUTION
Illustration of the Roles of Snow in the Evolution of the Winter Cover of a Lake,
W82-00267 2C

SPECIES DIVERSITY
The Prediction of Lacustrine Phytoplankton Diversity,
W82-00319 2H

SPECTROPHOTOMETRY
Interference of Sulphide in Inorganic Phosphate Determination in Natural Waters,
W82-00154 5A

SPECTROSCOPY
A Resonance Raman Method for the Rapid Detection and Identification of Bacteria in Water,
W82-00404 5A

SPENCER GULF
The Significance of the Submarine Geology of Upper Spencer Gulf, South Australia, to Environmental Decision-Making,
W82-00314 2L

SPILLWAYS
Model Study of a Box-Inlet Chute Spillway and SAF Stilling Basin,
W82-00046 8A

SPRINGVALE - BEAR CREEK
Final Environmental Impact Statement; Alternative Wastewater Treatment Systems for Rural Lake Projects; Case Study No. 3: Springvale-Bear Creek Sewage Disposal Authority, Emmet County, Michigan.
W82-00364 5D

SPRINKLER IRRIGATION
Water Application Uniformity of Hose Towed Traveler Irrigators,
W82-00296 3F

STABILIZATION PONDS
Virus Removal in Waste Stabilization Ponds in India,
W82-00121 5D

The Harvest of Microalgae from the Effluent of a Sewage Fed High Rate Stabilization Pond by Tilapia Nilotica. Part 1: Description of the System and the Study of the High Rate Pond,
W82-00455 5D

STAPHYLOCOCCUS AUREUS
Staphylococcus Aureus in Rural Drinking Water,
W82-00223 5B

STATE JURISDICTION
Summary of the New England Conference on Legal and Institutional Incentives to Small-Scale Hydroelectric Development, January 30-31, 1979, Boston, Massachusetts.
W82-00447 6E

Executive Summary, Legal Obstacles and Incentives to Small-Scale Hydroelectric Development in the Six Middle Atlantic States.
W82-00448 6E

STATISTICAL ANALYSIS
Water-Rock Partition Coefficients and the Composition of Natural Waters - A Reassessment,
W82-00284 2K

STATUTES
Legal Aspects of Subsidence Due to Well Pumping,
W82-00170 6E

STEEL INDUSTRY
Physical/Chemical Treatment of Blast Furnace Wastewaters Using Mobile Pilot Units,
W82-00378 5D

STEUBEN LAKES
Final Environmental Impact Statement; Alternative Wastewater Treatment Systems for Rural Lake Projects; Case Study No. 4: Steuben Lakes Regional Waste District, Steuben County, Indiana.
W82-00365 5D

STILLING BASIN
Model Study of a Box-Inlet Chute Spillway and SAF Stilling Basin,
W82-00046 8A

STOCHASTIC PROCESS
Analysis of Capacity Requirements for Storage Reservoirs: A Case Study,
W82-00341 6A

STORAGE CAPACITY
An Analysis of Reservoir Storage Contents for the Proposed Enlargement of Bumping Lake in Washington,
W82-00421 4A

STORAGE REQUIREMENTS
Analysis of Capacity Requirements for Storage Reservoirs: A Case Study,
W82-00341 6A

STORM RUNOFF
Hydrologic Data for Urban Studies in the Austin, Texas Metropolitan Area, 1979,
W82-00083 7C

STORM WATER
Modeling the Relationship Between Development and Storm Water and Nutrient Runoff,
W82-00260 2A

STORMS
Some Limiting Forms of the Poisson Distribution of Annual Station Precipitation,
W82-00132 2B

STREAM BANKS
Erodibility of Streambank Materials of Low Cohesion,
W82-00136 2J

STREAM ORDER
The Influence of Stream Order and Selected Stream Bed Parameters on Fish Diversity in Raystown Branch, Susquehanna River Drainage, Pennsylvania,
W82-00109 2E

STREAM POLLUTION
The Horse Creek Basin Project,
W82-00071 5G

STREAMFLOW
Report of the Annual Yield of the Arkansas River Basin for the Arkansas River Basin Compact, Arkansas--Oklahoma, 1980 Water Year,
W82-00012 6E

Quality of Water in Tibbee Creek and Tributaries Near West Point, Mississippi,
W82-00084 5B

Picloram Dissipation in a Small Southwestern Stream,
W82-00212 5B

Use of Flow-Duration Curves to Evaluate Effects of Urbanization on Streamflow Patterns on Long Island, New York,
W82-00416 4C

STREAMFLOW FORECASTING
The Limitations and Usefulness of Streamflow Generation Methods: A Case Study,
W82-00229 6A

STREAMS
Mudflows Resulting From the May 18, 1980, Eruption of Mount St. Helens, Washington,
W82-00003 5B

Relationship of Water Quality of Hudson River, New York, During Peak Discharges to Geologic Characteristics of Contributing Subbasins,
W82-00009 5B

Erosion and Sedimentation in the Kenai River, Alaska,
W82-00015 2J

A Comparison of Nitrogen in Shallow Ground Water from Sewered and Unsewered Areas, Nassau County, New York, from 1952 Through 1976,
W82-00277 5B

An Evaluation of Sources of Nitrogen as Causes of Ground-Water Contamination in Nassau County, Long Island,
W82-00279 5B

STREATOR
Final Environmental Impact Statement; Rehabilitation of Wastewater Facilities, Streator, Illinois.
W82-00361 5D

STRENGTH
Shear Strength of Rockfill,
W82-00116 8D

STRIP MINE WASTES
Hydraulic Properties of Coal and Related Materials, Northern Great Plains,
W82-00278 2F

STRIP MINES
Selective Overburden Placement,
W82-00053 5G

Premining Hydrologic Conditions of Five Southeastern Ohio Watersheds,
W82-00054 4C

The U.S. Geological Survey Coal Hydrology Program and the Potential of Hydrologic Models for Impact Assessments,
W82-00429 6E

SUBARCTIC ZONE
Aerial Biomass Distribution in an Undisturbed and Disturbed Subarctic Bog,
W82-00211 2C

SUBLETHAL EFFECTS
An Aquatic Respirometer for Use in Sublethal Studies,
W82-00122 5C

SUBMERGENCE
Geomorphic and Hydraulic Evolution of Tidal Creeks on a Subsiding Beach Ridge Plain, North Inlet, S.C.,
W82-00150 2L

SUBSIDENCE
Legal Aspects of Subsidence Due to Well Pumping,
W82-00170 6E

SUBSTRATES
Perpetual Shoals at the Entrance to Chesapeake Bay: Flow-Substrate Interactions and Mutually Evasive Net Currents,
W82-00149 2L

SUBSURFACE WATER
Possibilities of Using Helium and Tritium Surveys for Studying Recharge Conditions of Subsurface Waters,
W82-00302 7B

SUCCESSION
A Model of Natural and Man-Induced Changes in Open Freshwater Wetlands on the Massachusetts Coastal Plain,
W82-00397 2I

SULFATES
Sulfhydrolase Activity in Sediments of Wintergreen Lake, Kalamazoo County, Michigan,
W82-00241 2H

SULFIDES
Interference of Sulphide in Inorganic Phosphate Determination in Natural Waters,
W82-00154 5A

SULFUR COMPOUNDS
Reduction of Sulfur Compounds in the Sediments of a Eutrophic Lake Basin,
W82-00488 2H

SUNSPOTS
Solar Cycles and Erosional Events on the New South Wales Central and South Coasts,
W82-00318 2J

SURFACE RUNOFF
Planning Study to Model and Monitor Coal Pile Run-Off,
W82-00091 6A

Physical Effects of Vehicular Disturbances on Arid Landscapes,
W82-00111 4C

The Effects of Surface Slaty Fragments on Soil Erosion by Water,
W82-00471 2J

SURFACE WATER
Effects of the Mount St. Helens Eruption on the Benthic Fauna of the Toutle River, Muddy River, and Pine Creek Drainage Basins, Washington,
W82-00005 5C

Water Resources Investigations in New York--1980.
W82-00011 7C

Selected Hydrologic Data, Arkansas River Basin, Pueblo and Southeastern Fremont Counties, Colorado, 1975-80,
W82-00020 7C

Treatment of Florida Surface Waters for Use in Phosphate Beneficiation,
W82-00048 5D

Water Resources Data for New Hampshire and Vermont, Water Year 1980.
W82-00076 7C

Water Resources Data for West Virginia, Water Year 1980.
W82-00077 7C

Water Resources Data for Kansas, Water Year 1980--Volume 1. Missouri River Basin.
W82-00078 7C

Water Resources Data for Kansas, Water Year 1980--Volume 2. Arkansas River Basin.
W82-00079 7C

Water Resources Data for Texas, Water Year 1979--Volume 1. Arkansas River Basin, Red River Basin, Sabine River Basin, Neches River Basin, Trinity River Basin, and Intervening Coastal Basins.
W82-00080 7C

Water Resources Data for Texas, Water Year 1979--Volume 2. San Jacinto River Basin, Brazos River Basin, San Bernard River Basin and Intervening Coastal Basins.
W82-00081 7C

Water Resources Data for Texas, Water Year 1979--Volume 3. Colorado River Basin, Lavaca River Basin, Guadalupe River Basin, Nueces River Basin, Rio Grande Basin, and Intervening Coastal Basin.
W82-00082 7C

Quality of Water in Tibbee Creek and Tributaries Near West Point, Mississippi,
W82-00084 5B

Water-Resources Investigations of the U.S. Geological Survey in Wyoming, Fiscal Year 1980,
W82-00087 7C

Water-Resources Investigations of the U.S. Geological Survey in Colorado--Fiscal Year 1981.
W82-00088 7C

Areal Predictions of Water and Solute Flux in the Unsaturated Zone,
W82-00381 6A

Water in the Elizabethtown Area - A Study of Limestone Terrane in North-Central Kentucky,
W82-00413 5B

Radionuclide Concentrations in Streams in the Upper Blackfoot River Basin, Southeastern Idaho,
W82-00418 5A

Index to Active Hydrologic Data Collection Sites in Florida, 1980-81,
W82-00425 7C

The U.S. Geological Survey Coal Hydrology Program and the Potential of Hydrologic Models for Impact Assessments,
W82-00429 6E

SURFACTANTS
Use of the Electrolytic Respirometer to Measure Biodegradation in Natural Waters,
W82-00126 5A

Removal and Recovery of Organic Pollutants from the Aquatic Enviroment. 2. Removal and Recovery of Dodecylbenzenesulfonate from Aqueous Solution by Cross-Linked Poly(N-Benzyl-4-Vinylpyridinium Halide),
W82-00217 5D

SURVEYS
Hydraulic Gates: The State-of-the-Art,
W82-00332 8C

SUSPENDED SOLIDS
Polychlorinated Biphenyl Transport in the Hudson River, New York,
W82-00008 5B

The Effect of Centrifugation on the Suspended Particles of River Waters,
W82-00124 5A

Method for Recovering Viruses from River Water Solids,
W82-00200 5A

Lethality of a Suspended Clay to a Diverse Selection of Marine and Estuarine Macrofauna,
W82-00268 5C

Field Evaluation of a Swirl Degritter at Tamworth, New South Wales, Australia,
W82-00376 5F

Testing the Flocculation/Coagulation of Wastewater by Granulometric Analysis of Suspended Solids in the Water Using a Laser Diffraction Meter,
W82-00463 5D

SUSQUEHANNA RIVER BASIN
Flood Forecast and Warning System Evaluation, Susquehanna River Basin, New York, Pennsylvania and Maryland.
W82-00351 6F

SWAMPS
Vegetation and Nutrient Status of Northern Michigan Bogs and Conifer Swamps with a Comparison to Fens,
W82-00484 2I

Effects of Sewage Effluent Application on Litter Fall and Litter Decomposition in Cypress Swamps,
W82-00499 5E

SWIMMING POOLS
Distribution and Balance of Volatile Halogenated Hydrocarbons in the Water and Air of Covered Swimming Pools Using Chlorine for Water Disinfection,
W82-00128 5F

TADPOLES
Tadpoles as Indicators of Harmful Levels of Pollution in the Field,
W82-00478 5A

TAILWATER
Irrigation Tailwater Management,
W82-00392 3C

TANNERY WASTES
Advanced Biological Treatment of Tannery Wastewater,
W82-00337 5D

TAXONOMY
The Prediction of Lacustrine Phytoplankton Diversity,
W82-00319 2H

TENNESSEE
Geologic, Hydrologic and Chemical Data From Test Wells in the Dickson Area, Tennessee,
W82-00090 7C

Water Level Data for Wells in and Near Burial Ground 3, Oak Ridge National Laboratory, Tennessee, 1975-1979,
W82-00423 7C

The U.S. Geological Survey Coal Hydrology Program and the Potential of Hydrologic Models for Impact Assessments,
W82-00429 6E

TENNESSEE-TOMBIGBEE WATERWAY
Predicted Effects on Ground Water of Construction of Divide Cut Section, Tennessee-Tombigbee Waterway, Northeastern Mississippi Using a Digital Model,
W82-00428 2F

TERRACING
Terrace Planning Criteria for Runoff Control for Deep Loess Soil,
W82-00144 4D

TERROR LAKE
Final Environmental Impact Statement; Terror Lake Project No. 2743 - Alaska.
W82-00353 6G

TERTIARY TREATMENT
Continuous Bioregeneration of Granular Activated Carbon During the Anaerobic Degradation of Catechol,
W82-00408 5D

TERTIARY WASTEWATER TREATMENT
Phosphorus Dynamics of a Florida Freshwater Marsh Receiving Treated Wastewater,
W82-00108 5E

TEST WELLS
Geologic, Hydrologic and Chemical Data From Test Wells in the Dickson Area, Tennessee,
W82-00090 7C

TEXAS
Water Resources Data for Texas, Water Year 1979--Volume 1. Arkansas River Basin, Red River Basin, Sabine River Basin, Neches River Basin, Trinity River Basin, and Intervening Coastal Basins.
W82-00080 7C

Water Resources Data for Texas, Water Year 1979--Volume 2. San Jacinto River Basin, Brazos River Basin, San Bernard River Basin and Intervening Coastal Basins.
W82-00081 7C

Water Resources Data for Texas, Water Year 1979--Volume 3. Colorado River Basin, Lavaca River Basin, Guadalupe River Basin, Nueces River Basin, Rio Grande Basin, and Intervening Coastal Basin.
W82-00082 7C

Hydrologic Data for Urban Studies in the Austin, Texas Metropolitan Area, 1979,
W82-00083 7C

Preliminary Data From a Series of Artificial Recharge Experiments at Stanton, Texas,
W82-00085 7C

Optimal Design of Water Conveyance Systems,
W82-00160 6B

TEXTILE MILL WASTES
Textile Effluents Lose Their Color.
W82-00342 5D

THALLIUM
A Direct Differential Pulse Anodic Stripping Voltammetric Method for the Determination of Thallium in Natural Waters,
W82-00209 5A

THERMAL POLLUTION
Domestic Water Supplies for Power Plant Cooling,
W82-00180 6D

Field Experiments on Responses of a Freshwater, Benthic Macroinvertebrate Community to Vertebrate Predators,
W82-00477 5C

THERMAL STRESS
Field Experiments on Responses of a Freshwater, Benthic Macroinvertebrate Community to Vertebrate Predators,
W82-00477 5C

THERMODYNAMICS
Solution Species of Plutonium in the Environment,
W82-00163 5A

THIOCYANATES
Biological Oxidation of Aqueous Thiocyanate,
W82-00442 5D

THORIUM
Absorption of Radium and Thorium From New Mexico Uranium Mill Tailing Solutions,
W82-00040 5D

TIDAL EFFECTS
Neap-Spring Tide Sequences of Intertidal Shoal Deposits in a Mesotidal Estuary,
W82-00112 2L

TIDAL MARSHES
Geomorphic and Hydraulic Evolution of Tidal Creeks on a Subsiding Beach Ridge Plain, North Inlet, S.C.,
W82-00150 2L

TIDE LANDS
Effect of Agricultural Land Development on Drainage Waters in the North Carolina Tidewater Region,
W82-00094 5B

TILE DRAINAGE
Projected Tile Effluent Effects on the Oldman River,
W82-00333 5C

TIME SERIES ANALYSIS
Small-Scale Hydro in New England: 1960-1976,
W82-00169 6D

TOXICITY
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Biological Consequences of Treating a Lake with Hydrogen Peroxide on the Plankton Biocenosis (Biologiques Du Traitement D'Un Lac Avec Du Peroxyde D'Hydrogene Sur La Biocenose Planctonique),
W82-00305 2H

Development of Bioassay Procedures for Defining Pollution of Harbor Sediments,
W82-00387 5C

Clinical Tests in Aquatic Toxicology: State of the Art,
W82-00464 5A

Toxicity and Ecological Significance of Trace Elements in Aquatic Environments,
W82-00498 5B

TOXINS
An Aquatic Respirometer for Use in Sublethal Studies,
W82-00122 5C

Effectiveness of Activated Carbon for Removal of Toxic and/or Carcinogenic Compounds From Water Supplies,
W82-00383 5F

TRACE ELEMENTS
Trace Metal Geochemistry in Sediments from the Miramichi Estuary, New Brunswick,
W82-00236 5A

TRACE LEVELS
Identification of Organic Compounds in a Mutagenic Extract of a Surface Drinking Water by a Computerized Gas Chromatography/Mass Spectrometry System (GC/MS/COM),
W82-00256 5A

TRACE METALS
Characterization of Soluble and Colloidal-Phase Metal Complexes in River Water by Ultrafiltration. A Mass-Balance Approach,
W82-00480 5A

Toxicity and Ecological Significance of Trace Elements in Aquatic Environments,
W82-00498 5B

TRACERS
Carbon Isotopes as Indicators of the Source and Fate of Carbon in Rivers and Estuaries,
W82-00033 5B

Chemical Indicators of Organic River Sources in Rivers and Estuaries,
W82-00035 5B

TRAINING
National Water Data Exchange (NAWDEX) System 2000 Data Retrieval Manual,
W82-00420 10B

TRANSMISSIVITY
Aquifer Parameter Identification with Optimum Dimension in Parameterization,
W82-00131 2F

TRANSPIRATION CONTROL
Reduced Transpiration and Increased Water Efficiency by Diuron in Corn (Zea Mays),
W82-00196 2D

TRAP EFFICIENCY
Sediment Trap Dynamics and Calibration: A Laboratory Evaluation,
W82-00104 7B

Field Assessment of Sediment Traps,
W82-00105 7B

TRIHALOMETHANES
An Alternative Solution to the THM Problem,
W82-00072 5F

Temporal Variations in Trihalomethane Content of Drinking Water,
W82-00255 5A

Ozone Treatment of Potable Water--Part 2,
W82-00452 5F

TROPHIC LEVEL
Occurrence of Aphanomyces Ovidestruens, a Fungus Parasitic on Copepods, in Two Eutrophic Lakes,
W82-00304 2H

TYEE LAKE PROJECT
Final Environmental Impact Statement; Tyee Lake Project FERC No. 3015 - Alaska.
W82-00354 6G

ULTRAFILTRATION
Characterization of Soluble and Colloidal-Phase Metal Complexes in River Water by Ultrafiltration. A Mass-Balance Approach,
W82-00480 5A

UNDERGROUND WASTE DISPOSAL
Strategy for Radioactive Waste Disposal in Crystalline Rocks,
W82-00299 5E

Deep Well Injection of Industrial Wastes,
W82-00475 5E

UNSATURATED FLOW
A Comparative Study of Three Forms of the Richard Equation Used for Predicting One-Dimensional Infiltration in Unsaturated Soil,
W82-00328 2G

URANIUM
Computer Modeling of Fluid Flow During Production and Environmental Restoration Phases of In Situ Uranium Leaching,
W82-00043 6A

Ground-Water Flow and Uranium in Colorado Plateau,
W82-00282 2F

URBAN HYDROLOGY
Hydrologic Data for Urban Studies in the Austin, Texas Metropolitan Area, 1979,
W82-00083 7C

URBAN RUNOFF
Quarterly Progress Report, Nationwide Urban Runoff Program.
W82-00044 5G

Hydrologic Data for Urban Studies in the Austin, Texas Metropolitan Area, 1979,
W82-00083 7C

Modeling the Relationship Between Development and Storm Water and Nutrient Runoff,
W82-00260 2A

Use of Flow-Duration Curves to Evaluate Effects of Urbanization on Streamflow Patterns on Long Island, New York,
W82-00416 4C

URBANIZATION
Use of Flow-Duration Curves to Evaluate Effects of Urbanization on Streamflow Patterns on Long Island, New York,
W82-00416 4C

USSR
Use of River Waters That Did Not Reach the Aral Sea as a Consequence of Economic Activity During 1961-1975,
W82-00190 4A

VALVES
The Case for Specifying AWWA Butterfly Valves.
W82-00213 8C

VEGETATION
SEASAT SAR Response from Water Resources Parameters,
W82-00101 7B

A Model of Natural and Man-Induced Changes in Open Freshwater Wetlands on the Massachusetts Coastal Plain,
W82-00397 2I

VEGETATION EFFECTS
Flow Resistance in Vegetated Waterways,
W82-00152 2E

VERMONT
Water Resources Data for New Hampshire and Vermont, Water Year 1980.
W82-00076 7C

VERNA
Hydrogeologic Data from Test Drilling near Verna Beach, Florida, 1978,
W82-00424 2F

VIBRIO
Incidence of Vibrio Alginolyticus and Bacteria of Sanitary Significance in the Bering Sea,
W82-00490 5A

VIRGINIA
Water Resources of Prince William Forest Park, Virginia,
W82-00026 7C

VIRUSES
Virus Removal in Waste Stabilization Ponds in India,
W82-00121 5D

Influence of Estuarine Sediment on Virus Survival Under Field Conditions,
W82-00199 5A

Method for Recovering Viruses from River Water Solids,
W82-00200 5A

Improved Method and Test Strategy for Recovery of Enteric Viruses from Shellfish,
W82-00219 5A

Evaluation of the Overland Runoff Mode of Land Wastewater Treatment for Virus Removal,
W82-00220 5B

Technique for Determining Total Bacterial Virus Counts in Complex Aqueous Systems,
W82-00222 5A

Concentration of Poliovirus in Water by Molecular Filtration,
W82-00246 5A

Recovery of Indigenous Viruses from Wastewater Sludges, Using a Bentonite Concentration Procedure,
W82-00271 5D

The Effect of Bentonite Clay on Ozone Disinfection of Bacteria and Viruses in Water,
W82-00292 5F

Viral Transport Through Soil Columns Under Conditions of Saturated Flow,
W82-00295 5B

Silicates as Nonspecific Adsorbents of Bacteriophage: A Model for Purification of Water From Viruses,
W82-00350 5F

Application of a Multiple Alginate Filter Method for the Determination of Water Viruses Concentration (Conception D'Une Membrane Filtrante a Base D'Alginate Pour La Concentration Des Virus Hydriques),
W82-00458 5A

VOLCANIC ASH
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Mount St. Helens Volcanic-Ash Fall in the Bull Run Watershed, Oregon, March-June 1980,
W82-00002 5B

Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

VOLCANOES
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Mount St. Helens Volcanic-Ash Fall in the Bull Run Watershed, Oregon, March-June 1980,
W82-00002 5B

Mudflows Resulting From the May 18, 1980, Eruption of Mount St. Helens, Washington,
W82-00003 5B

Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

Effects of the Mount St. Helens Eruption on the Benthic Fauna of the Toutle River, Muddy River, and Pine Creek Drainage Basins, Washington,
W82-00005 5C

Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

Effects of Volcanism on the Glaciers of Mount St. Helens,
W82-00007 2C

VOLCANOES

The Aftermath at Longview,
W82-00073 5C

WALES
A Successful Transfer,
W82-00309 4A

WARNING SYSTEMS
Flood Forecast and Warning System Evaluation, Susquehanna River Basin, New York, Pennsylvania and Maryland.
W82-00351 6F

WASHINGTON
Toxicity of Mount St. Helens Ash Leachate to a Blue-Green Alga,
W82-00001 5C

Mudflows Resulting From the May 18, 1980, Eruption of Mount St. Helens, Washington,
W82-00003 5B

Channel Conditions in the Lower Toutle and Cowlitz Rivers Resulting From the Mudflows of May 18, 1980,
W82-00004 5B

Effects of the Mount St. Helens Eruption on the Benthic Fauna of the Toutle River, Muddy River, and Pine Creek Drainage Basins, Washington,
W82-00005 5C

Effects of Mount St. Helens Eruption on Selected Lakes in Washington,
W82-00006 2H

Effects of Volcanism on the Glaciers of Mount St. Helens,
W82-00007 2C

An Analysis of Reservoir Storage Contents for the Proposed Enlargement of Bumping Lake in Washington,
W82-00421 4A

WASTE CHARACTERISTICS
Slagging Fixed-Bed Gasifier (SFBG) Wastewater Pretreatment,
W82-00433 5D

WASTE DISPOSAL
Water-Related Environmental Control Requirements at Municipal Solid Waste-to-Energy Conversion Facilities,
W82-00037 5D

Lining of Waste Impoundment and Disposal Facilities.
W82-00099 5E

Slash Treatment After Clearcutting Lodgepole Pine Affects Nutrients in Soil Water,
W82-00130 4C

Anaerobic Treatment of Human Waste in Northern Communities,
W82-00249 5E

WASTE RECOVERY
Survival of Eggs and Larvae of Swine Nematode Parasites in Aerobic and Anaerobic Waste Treatment Systems,
W82-00161 5D

Leachates from Solid Waste Recovery Operations,
W82-00167 5D

WASTE STORAGE
Lining of Waste Impoundment and Disposal Facilities.
W82-00099 5E

WASTE TREATMENT
Land Restoration Following Oil-Well Drilling,
W82-00057 5D

Methane Production from Ozonated Pulp Mill Effluent,
W82-00155 5D

Anaerobic Treatment of Human Waste in Northern Communities,
W82-00249 5E

WASTE WATER TREATMENT
Design, Evaluation and Effluent Water Quality Analysis of Three Oyster Shellstock Washers,
W82-00406 5D

Continuous Bioregeneration of Granular Activated Carbon During the Anaerobic Degradation of Catechol,
W82-00408 5D

WASTEWATER
Evaluation of the Overland Runoff Mode of Land Wastewater Treatment for Virus Removal,
W82-00220 5B

Enumeration of Potentially Pathogenic Bacteria from Sewage Sludges,
W82-00221 5A

Technique for Determining Total Bacterial Virus Counts in Complex Aqueous Systems,
W82-00222 5A

WASTEWATER ANALYSIS
The Analysis of Oil Shale Wastes: A Review,
W82-00388 5A

WASTEWATER COMPOSITION
Assessment of Oil Shale Retort Wastewater Treatment and Control Technology - Phases I and II,
W82-00390 5B

WASTEWATER DISPOSAL
Cropping Systems for Treatment and Utilization of Municipal Wastewater and Sludge,
W82-00097 5E

Phosphorus Dynamics of a Florida Freshwater Marsh Receiving Treated Wastewater,
W82-00108 5E

Experimental Studies on the Effect of Arsenic on Microbial Degradation of Organic Matter and Algal Growth,
W82-00237 2H

Final Environmental Impact Statement, City of Portage Wastewater System, Columbia County, Wisconsin.
W82-00356 6G

State-of-the-Art of Liquid Waste Disposal for Geothermal Energy Systems: 1979,
W82-00375 5E

Sodium-Potassium Ratios in Soil Solution and Plant Response Under Saline Conditions,
W82-00469 3C

Anaerobic Methane Oxidation: Occurrence and Ecology,
W82-00218 2H

WISCONSIN UNIV.-MADISON. WATER CHEMISTRY LAB.
Factors Affecting Phosphorus Release from Intact Lake Sediment Cores,
W82-00251 2H

WISCONSIN UNIV.-MADISON. WATER RESOURCES CENTER.
An Empirical Equation for Predicting Soluble Phosphorus Loads from Agricultural Watersheds,
W82-00134 5B

WISCONSIN UNIV.-SUPERIOR.
Development of Bioassay Procedures for Defining Pollution of Harbor Sediments,
W82-00387 5C

WOODWARD-CLYDE CONSULTANTS, SAN FRANCISCO, CA.
Quarterly Progress Report, Nationwide Urban Runoff Program.
W82-00044 5G

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 15, NUMBER 2
FEBRUARY 1, 1982

W82-00501 -- W82-01100
CODEN: SWRABW

DEPOSITORY

APR 5 1982

UNIVERSITY OF ILLINOIS
AT URBANA-CHAMPAIGN

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Office of Water Research and Technology, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Office of Water Research and Technology, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Office of Water Research and Technology,
U.S. Department of the Interior

VOLUME 15, NUMBER 2
FEBRUARY 1, 1982

W82-00501 -- W82-01100

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through August 31, 1983.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Office of Water Research and Technology. The cumlative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE OFFICE OF WATER RESEARCH AND TECHNOLOGY DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

Office of Water Research and Technology

UNIVERSITY OF ILLINOIS LIBRARY

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

GRAVITATIONAL STABILITY OF WATER OVER STEAM IN VAPOR-DOMINATED GEOTHERMAL SYSTEMS,
Aerospace Corp., Los Angeles, CA. Space Science Lab.
G. Schubert, and J. M. Straus.
Journal of Geophysical Research, Vol 85, No B11, p 6505-6512, November, 1980. 7 Fig, 13 Ref.

Descriptors: *Geothermal studies, *Water vapor, *Stability analysis, Geothermal resources, Mathematical studies, Condensates, Permeability.

The gravitational stability of a condensate or water layer overlying steam in a vapor-dominated geothermal system was investigated. Linear stability analysis was carried out on superposed layers of immiscible fluids in a porous medium and demonstrated that the heavy over light configuration is always unstable. A similar stability analysis was carried out for the case in which the interface separating the fluid layers is a phase change. The phase change was found to stabilize the heavy over light configuration. The conditions under which this stabilization occurs are quantified and applied to the water over steam situation characteristic of vapor-dominated geothermal systems. The condensate layer can be stabilized if the permeability near its base is no larger than about 40 sq nm (0.04 millidarcy). The special behavior of the phase change interface between water and steam permits the stabilization of the system with a nonzero permeability. (Small-FRC)

BUOYANCY FORCE REVERSALS IN VERTICAL NATURAL CONVECTION FLOWS IN COLD WATER,
State Univ. of New York at Buffalo. Dept. of Mechanical Engineering.
V. P. Carey, B. Gebhart, and J. C. Mollendorf.
Journal of Fluid Mechanics, Vol 97, No 2, p 279-297, March, 1980. 9 Fig, 11 Ref.

Descriptors: *Temperature effects, *Natural flow, *Buoyancy, Mathematical studies, Hydrodynamics, Saline water, Ice, Freezing, Melting.

Calculated transport is compared to experimental transport for laminar buoyancy-induced flows driven by thermal transport to or from a vertical isothermal surface in cold pure and saline water. Specifically, the consequences of temperature conditions wherein the buoyance force reverses across the thermal region owing to the presence of a density extremum are explored. This is a common condition in terrestrial waters and in technological processes utilizing cold water. A nonlinear density equation of state for both pure and saline water is presented which permits an accurate treatment of flows for bounding temperatures up to 20 deg C at salinity levels from 0 to 40 ppt and pressure levels from 1 to 1000 bars. Applications include the melting or slow freezing of a vertical ice surface in pure water as well as a heated or cooled vertical isothermal surface in pure or saline water. Calculated transport agreed well with experimental results. The results indicate that such flows are relatively weak but can lead to early laminar instability. (Small-FRC)

FLOW ANALYSIS OF MODELS OF THE HUBBARD BROOK ECOSYSTEM,
Massachusetts Univ., Amherst. Dept. of Forestry and Wildlife Management.
J. T. Finn.
Ecology, Vol 61, No 3, p 562-571, 1980. 7 Fig, 7 Tab, 19 Ref.

Descriptors: *Flow characteristics, *Ecosystems, Model studies, Flow measurement, Flow profiles, Flow rates, Flow system, Cycling nutrients, Nutrients, Energy.

Flow analysis, a method of tracing flows of materials through a system, was applied to some of the Hubbard Brook data to determine the amount cycled per year of several elements and energy at Hubbard Brook compared to the total amount of each flowing per year in the system and also determine the pattern of nutrient and energy flow in the ecosystem. Three different models of calcium flow were compared to judge the effect of small differences in model structure on cycling and flow pattern. When all three models were analyzed using the same nutrient flux data, flow measures became very close, in spite of structural differences in the models. For these models, flow values were more important than the architecture of the models in determining cycling and flow characteristics. Flow analysis offers a new set of tools to investigators of biogeochemical cycling, which enabls comparisons between elements and across systems, and which also may serve as an aid in evaluating models of cycling. AQUASOLS: THE BEHAVIOR OF SMALL PARTICLES IN AQUATIC SYSTEMS,
Johns Hopkins Univ., Baltimore, MD.
C. R. O'Melia.
Environmental Science and Technology, Vol 14, No 9, p 1052-1060, September, 1980. 11 Fig, 3 Tab, 13 Ref.

Descriptors: *Physical properties, *Water pollution, Reviews, Water resources management, Water demand, Water quality, *Particulate matter, Water treatment facilities, Wastewater treatment, Water transport, Conveyance structures, Aqueducts, Aquifers, Natural waters, Lakes, Temperature effects.

This article describes the physical processes that affect transport and fate of solid particles in aquatic systems and illustrates, using case studies, the present understanding of these processes and the extent of their effects. Three physical processes are considered: Brownian or molecular diffusion, in which random motion of small particles is brought about by thermal effects; fluid shear (either turbulent or laminar): and gravity, which produces vertical transport of particles and depends on the buoyant weight of the particles. Four case studies are summarized. Two are examinations of particle deposition at water-solid interfaces; filtration by packed beds in laminar flow, and deposition on pipe walls in turbulent flow. The other two examples consider particle transport within aquatic systems: a water treatment plant and a lake. Current available evidence suggests that most pollutants in water are particles or are associated with particles. These particles are governed by physical processes. Knowledge permits these processes to be described and controlled in treatment and transport systems for water supply and wastewater disposal. By extending these concepts to natural aquatic systems, new insights will be found into the functioning of the natural systems and the flow of materials through them. This knowledge will improve man's management of these systems and enable him to more successfully control his impact on them. (Baker-FRC)

ELECTRICAL ASPECTS OF ADSORBING COLLOID FLOTATION. XI. SURFACTANT ADSORPTION ISOTHERMS, PARTICLE DISPLACEMENT, AND DIFFERENTIAL CAPACITANCE,
Vanderbilt Univ., Nashville, TN. Dept. of Chemistry.
J. E. Kiefer, and D. Wilson.
Separation Science and Technology, Vol 15, No 1, p 57-74, 1980. 14 Fig, 25 Ref.

Descriptors: *Bubbles, Statistical methods, *Adsorption, Isotherms, Temperature gradient, *Surfactants, Sediment-water interfaces, Electrical properties, *Air-water interfaces.

The theory of surfactant adsorption of floc particles at the air-water interface was explored. First the adsorption of surfactant onto floc particles to form a hemimicelle was examined; this renders the particles hydrophobic and permits bubble attachment to occur. Statistical mechanics were used to calculate adsorption isotherms of ionic surfactants on charged solid-water interfaces. The effects of coulombic repulsions between the ionic heads of the surfactant species are taken into account, as are the van der Waals attractions of their hydrocarbon tails. A 'squeeze-out' mechanism by means of which viscous drag forces acting tangentially to the surface of a rising bubble may detach floc particles from it is examined. A nonideal Poisson-Boltzmann equation is used to calculate the differential capcitance of the electric double layer at an interface. (Baker-FRC)

IDENTIFICATION OF STREAMFLOW STOCHASTIC MODELS,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
J. D. Salas, J. T. B. Obeysekera, and R. A. Smith.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY7, p 853-866, July, 1981. 2 Fig, 5 Tab, 35 Ref.

Descriptors: *Stochastic processes, *Streamflow forecasting, *Model studies, Niger River, Rivers, Hydrologic models, Watersheds, Rainfall-runoff relationships, Groundwater, Autoregressive Moving Average Model.

This paper presents a method for choosing an appropriate stochastic model for annual streamflows. The type of model is chosen on the basis of a conceptual physical representation of a natural watershed, and the form, on the basis of recently developed R-functions and S-functions. Under certain assumptions, for an ARMA (p,q) (Autoregressive Moving Average Model) precipitation input the groundwater storage is an ARMA (p + 1, q) process and the streamflow is an ARMA (p + 1, q + 1) process. In general, such groundwater and streamflow processes belong to the class of restricted ARMA processes in the sense that their parameter space is a subspace of that corresponding to the general ARMA models. An example shows how the annual flows of the Niger River at Koulicoro, Africa, can be modeled by ARMA. (Cassar-FRC)

A GEOMORPHOLOGIC SYNTHESIS OF NONLINEARITY IN SURFACE RUNOFF,
Mississippi Univ., University. Dept. of Civil Engineering.
C. T. Wang, V. K. Gupta, and E. Waymire.
Water Resources Research, Vol 17, No 3, p 545-554, June, 1981. 7 Fig, 1 Tab, 24 Ref.

Descriptors: *Surface runoff, *Geomorphology, Rainfall-runoff relationships, Hydrographs, Runoff, Rainfall intensity, Predictions, Basins, River basins, Illinois, *Nonlinear programming.

URBANA, IL. LIBRARY

A nonlinear (quasi-linear) geomorphic approach for modeling the rainfall-runoff process for a basin was developed by generalizing a recently developed linear geomorphic approach (Gupta et al., 1980). The nonlinearity in the transformation enters in partly through the dependence of the mean holding time on the rainfall intensity. Under an assumed first approximation that this dependence is the sole source of nonlinearity, an explicit quasi-linear representation results for the rainfall-runoff transformation. The kernel function of this transformation can be termed the instantaneous response function, whereas the linear rainfall-runoff transformation is termed the instantaneous unit hydrograph. Analysis of a small basin showed agreement between the quasi-linear theory results and the prediction from the kinematic wave approach. For two large (1100 sq miles) basins in Illinois, predictions from the quasi-linear approach compared well with observed flows. Computations of the measure of nonlinearity for four basins showed that it approaches 2/3 with decreasing basin size and zero with increasing basin size. A straight line was formed with a semilog plot of nonlinearity vs. square root of basins area. (Cassar-FRC)
W82-00604

MULTIVARIATE HYDROLOGIC TIME SERIES ANALYSIS,
Ottawa Univ. (Ontario). Dept. of Civil Engineering.
C. T. Hsu, and K. Adamowski.
Advances in Water Resources, Vol 4, No 2, p 83-95, June, 1981. 11 Fig, 2 Tab, 16 Ref.

Descriptors: *Runoff, *Mathematical models, *Watershed management, Model studies, Statistical analysis, Rainfall, Hydrology, Meteorological data collection, *Streamflow forecasting.

A multivariate watershed hydrologic system model was developed which involves meteorological data as the input and river flow as the output. Monthly hydrological time series of runoff, temperature, and precipitation were analyzed. This autoregressive-moving average transfer function model was adequate to model the monthly watershed system. The accuracy of estimation of runoff characteristics was enhanced with the use of the meteorological and hydrometric data. For watersheds with large storage, the improvement was not pronounced. The large storage effect plays a dominant role in the generating process of system response, and the contribution from external disturbances will be damped out before it becomes significant. To model a multivariate watershed hydrologic system, a combined deterministic-statistical approach could be used. For example, net precipitation rather than gross precipitation could be used as input. (Small-FRC)
W82-00647

STUDY OF THE FACTORS AND REGULARITIES OF RIVER RUNOFF ON THE BASIS OF DATA OF OBSERVATIONS ON REPRESENTATIVE BASINS,
Hydrometeorological Service of the USSR, Moscow.
V. D. Komarov.
Water Resources (English Translation), Vol 7, No 4, p 293-303, July-August, 1980. 8 Fig, 8 Ref. Translated from Vodnye Resursy, No 4, p 5-18, July-August, 1980.

Descriptors: *Runoff forecasting, *Representative basins, *Snowmelt, Basins, Hydrologic models, Russia, Spatial distribution, Forest watersheds, Watersheds, Small watersheds, Rivers, Snow cover, Soil moisture, Freezing, Vegetation.

River runoff observations were started in representative basins in Russia in 1924. There are 10 water balance stations in European Russia, and others in Central Asia, the Far East, and Maritime Territory. The major concern in the European sector is the spring runoff. The observation program includes runoff measurements, snow surveys, depth of freezing, soil moisture content, groundwater level, and meteorological data. By considering two types of spatial inhomogeneity, methods of calculation for runoff can be improved. The first is the variation in physiographic conditions, for example, treeless and forested zones. The second is the variation within each part of the water basin equivalent of snow cover, soil moisture content, depth of freezing, storage capacity of closed depressions, etc. The Moscow water balance station is used as an illustration in choosing representative basins. It is not necessary to choose a totally treeless basin and a totally forested basin. Instead, the Medvenka River basin (area 21.5 sq km, forest 0.26) and the Zakza River basin (area 17.0 sq km, forest 0.73) were chosen. These basins are similar in physiographic conditions, with the exception of forest cover, and are representative of larger basins. Relationships derived from these two representative basins are applied to the 18,000 sq km Cheptsa River basin, forest coverage 0.26, similar to the two representative basins in soils, relief, and vegetation. The calculated runoff agreed well with that observed in the Cheptsa basin--1974, 172 and 162 mm; 1975, 79 and 77 mm; and 1976, 59 and 56 mm. (Cassar-FRC)

EFFECTS OF TROPICAL CYCLONE WALLY IN SOUTHEAST VITI LEVU, FIJI, EASTER 1980,
Victoria Univ., Wellington (New Zealand).
R. Howorth, M. J. Crozier, and I. J. Grant.
Search, Vol 12, No 1/2, p 41-43, January/February, 1981. 1 Fig, 1 Tab, 3 Ref.

Descriptors: *Landslides, *Tropical cyclones, *Excess rainfall, Rainfall, Cyclones, Storms, Rainstorms, Flooding, Floods, Viti Levu, *Fiji Islands.

As part of a slope-stability study being carried out in the Fiji Islands, landslides which occurred on Viti Levu during the time the tropical cyclone Wally passed through the area were investigated. Massive and extensive landslides occurred in the area after a rainfall exceeding 500 mm over a two-day period. The average monthly rainfall for this area is 263 mm. Severe flooding caused flood water depths of 1.0-1.5 m on the Navua River delta. Fifteen people were killed and 113 villages were affected. Times of peak discharge of the coastal rivers were coincident with the landslides. Most of the landslides occurred on the evening of April 4th. Total rainfall for April 4 was 261.8 mm, for April 3, 307.8 mm, and for April 2, 111.4 mm. Most of the slides affected only regolith, and in only one case was in situ bedrock involved. Most of the slides occurred just after nightfall, between 1800 and 2200 hr. The rain stopped at about the same time, which may have permitted the ground to regain stability. (Small-FRC)
W82-00670

POSSIBILITY OF USING TRITIUM FOR STUDYING GLOBAL CIRCULATION OF ATMOSPHERIC MOISTURE,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
V. I. Ferronskii, L. Yu. Ivanova, Kh. A. Kikichev, L. P. Kuznetsova, and V. V. Romanov.
Water Resources (English Translation), Vol. 7, No. 5, p 478-482, September/October, 1980. 3 Fig, 12 Ref. Translated from Vodnye Resursy, No. 5, p 171-177, Setember/October, 1980.

Descriptors: *Atmospheric moisture, *Tritium, Measurement techniques, Air circulation, Isotopic tracers, Tracers, Water vapor, Atmospheric, Global circulation.

The suitability of the isotopic tracer method for use in studying global circulation of atmospheric moisture was investigated, using as a lable the tritium (T) produced during the low-power atmospheric nuclear in China on March 14, 1978. Tritium which enters the atmosphere as a result of nuclear explosions quickly reacts with atmospheric oxygen to form the water molecular HTO. This tritium water vapor participates in the circulation of air masses and moisture in the atmosphere, permitting tracking of the movement of the incorporating air mass until the tritium label is removed by dispersion of air particles and moisture. The sampling method used is based on adsorption of water vapor during pumping of air through a drying agent, followed by electrolysis and measurement of the tritium concentration by a liquid scintillation spectrometer. The higher level of radioactivity in the atmosphere and precipitation permitted tracking of the radioactive cloud for two weeks after the explosion. Analysis of the movement of the labelled air mass demonstrated that the time of circulation of water vapor around the earth is a natural phenomenon as well as a theoretical concept. Under certain conditions of atmospheric circulation, packets of moisture may exist and be moved over long periods of time without substantial dispersion, at least in the substratosphere. The isotopic tracer method permits tracking of the movement of air masses and atmospheric moisture both in cloudy and rainy and in clear and dry weather. These results indicate that tritium, which can be injected at the required height by ordinary technical means, can be used as a tracer in experimental studies of global circulation of air masses and atmospheric water vapor. (Carroll-FRC)
W82-00863

A COMPARISON OF RAINFALL-RUNOFF MODELS,
Western Australia Univ., Nedlands.
W. D. Weeks, and R. H. B. Hebbert.
Nordic Hydrology, Vol 11, No 1, p 7-24, 1980. 10 Fig, 4 Tab, 16 Ref.

Descriptors: *Rivers, *Model studies, *Rainfall-runoff relationships, Australia, Time series analysis, Mathematical studies, Sacramento model, Monash model, Stanford model, Boughton model, *Comparison studies.

Five rainfall-runoff models were tested on 3 catchments in southwest Western Australia by calibration with 6 years of data followed by testing on a further 6-7 years of extra data. The Boughton Model, a simple conceptual model, was unacceptable because it was developed for catchments vastly different from the rivers studied. The Sacramento, Stanford, and Monash models, sophisticated conceptual models, and a black box or purely mathematical method involving a recursive time series algorithm all performed in a satisfactory manner. The straightforward Sacramento and the simple time series analysis are recommended for the larger rivers; the Monash and Stanford models, for the smaller catchments, Monash being marginally better. The Sacramento, with finite storages, and the time series analysis, with no provision for baseflow, performed poorly on the very small river. (Cassar-FRC)
W82-00911

SIMULATION OF LAKE-WATERSHED SYSTEMS, I. DESCRIPTION AND SENSITIVITY ANALYSIS OF THE MODEL,
Alberta Univ., Edmonton. Dept. of Geology.
A. S. Crowe, and F. W. Schwartz.
Journal of Hydrology, Vol 52, No 1/2, p 71-105, June, 1981. 15 Fig, 1 Tab, 19 Ref.

Descriptors: *Watersheds, *Model studies, Lakes, Groundwater, Hydrology, Water quality, Salinity, Lake morphology, Precipitation, Evaporation, Surface runoff, Flow discharge, *Lake-watershed systems.

A hydrologic transport model has been developed which is oriented primarily toward lakes and is used to examine the role that various climatic and watershed variables play in controlling the physical and chemical hydrology. The hypothetical lake-watershed system defined for the sensitivity analysis has characteristics similar to lakes in the prairie parkland of Canada. The lumped response model presented is able to simulate the hydrologic responses of a lake-watershed system to variations

in precipitation, potential evaporation and air temperatures. It operates by routing water through an idealized system. From the use of this model several conclusions were drawn. The water level and salinities of the lake depended on the general lake morphometry. Variations in groundwater chemistry over a part of the watershed do not significantly alter the salinity of the hypothetical prairie lake. Large decreases or increases in the quality of groundwater over the entire watershed will alter the salinity of the lake. The unsaturated zone primarily controls the amount of water percolating to the groundwater zone and thus indirectly influences the amount of groundwater discharged to the lake. As the amount of a watershed covered by an unsaturated zone decreases, the amount of groundwater recharge increases. Increasing the proportion of this hypothetical watershed that is impervious causes precipitation to flow directly to the lake, decreasing salinity, increasing fluctuations of lake levels and generally increasing the lake stage. Variations in precipitation and potential evaporation do not cause large fluctuations in lake levels and salinity in the large watershed used in this analysis, but would in a small lake-watershed system. (Baker-FRC)
W82-00926

SIMULATION OF LAKE-WATERSHED SYSTEMS, II. APPLICATION TO BAPTISTE LAKE, ALBERTA, CANADA,
Alberta Univ., Edmonton. Dept. of Geology.
A. S. Crowe, and F. W. Schwartz.
Journal of Hydrology, Vol 52, No 1/2, p 107-125, June, 1981. 8 Fig, 6 Tab, 21 Ref.

Descriptors: *Watersheds, *Model studies, Lakes, Groundwater, Groundwater movement, Surface-groundwater relations, Lake morphology, *Lake-watershed systems.

The applicability of a hydrologic simulation model for evaluating an actual lake-watershed system was investigated at the Baptiste Lake system in east-central Alberta, Canada. This is an important potential recreational development area, and a large data base for the area already exists. The watershed covers an area of 318 square kilometers, of which 58% is forest, 25% is standing water consisting of the subject lake, swamps and rivers, 16% is agricultural land, and less than 1% is cottage development along the lake shore. Land to the north and east of the lake is farm land, while that to the south and west is mostly swamp and forest. With the model it was possible to recapitulate a 6-year history of lake level fluctuations. The predicted and measured lake levels have a mean absolute difference of less than 0.1 meter. The cyclical character of water level fluctuations on an annual basis was also preserved in the simulation results. Although only a relatively short record of lake chemistry was available, the model was able to simulate with a reasonable degree of accuracy the total dissolved solids content of the lake. The study suggests that groundwater inflow to the lake comprises about 13% of the annual inflow from all sources and is not unreasonable for lakes in this kind of hydrological setting. (Baker-FRC)
W82-00927

ADAPTIVE HYDROLOGICAL FORECASTING - A REVIEW,
Institute of Hydrology, Wallingford (England).
P. E. O'Connell, and R. T. Clarke.
Hydrological Sciences Bulletin, Vol 26, No 2, p 179-205, June, 1981. 3 Fig, 2 Tab, 40 Ref.

Descriptors: *Runoff forecasting, *Rainfall, *Mathematical models, Forecasting, Hydrology, River basins, Reviews.

A variety of models and parameter estimation algorithms for hydrological forecasting are reviewed, including a discussion of the assumptions underlying them and some problems encountered in their application. Four models were applied to 2 months of half-hourly rainfall and runoff data for the Hirnant sub-basin of the River Dee. The four models were: Model A, a version of the River Dee sub-basin model; Model B, the simple nonlinear conceptual model used by Moore and Weiss (1980); Model C, a linear transfer function model with time variant parameters; and Model D, a selftuning predicator with PERLOG input. Models A and B had the smallest error variances, but D performed best in terms of standardized Q and S statistics. The standard assumptions of independence and identical distribution for system noise are not justified for hydrological systems. There are considerable unsolved estimation problems in real time forecasting, but it may be most beneficial to find a better representation of the spatial variation in rainfall and its effects of streamflow. (Small-FRC)
W82-00984

OVERLAND FLOW ON A DIVERGING SURFACE,
Mississippi State Univ., Mississippi State. Dept. of Civil Engineering.
N. Agiralioglu, and V. P. Singh.
Hydrological Sciences Bulletin, Vol 26, No 2, p 137-147, June, 1981. 7 Fig, 2 Tab, 15 Ref.

Descriptors: *Overland flow, *Mathematical models, *Groundwater basins, Kinetics, Hydrographs, Mathematical studies, Topography.

A basin diverging flow model is presented which utilizes kinetic wave theory. A first order explicit finite difference scheme is used to solve the kinematic equations. The model is compared with the plane model. The two models yield different concentration times and hydrographs that differ in shape, depending upon the degree of divergence. The rising hydrograph rises faster for the diverging model than for the plane model. The reverse is true for the recession hydrograph. Also, the diverging model gave longer times of concentration than the plane model. In natural basins that have divergence in their geometric configurations, the divergence model may predict hydrographs reasonably well. Suitable basins are both rural and urban with upland portions which diverge and lower portions which converge. A diverging basin's response is similar to that of a cascade of planes of decreasing size, and its descrete analog is a system composed of unequal nonlinear reservoirs used in parametric hydrology. TRACE CONSTITUENTS IN CLOUD WATER, RAINWATER AND AEROSOL SAMPLES COLLECTED NEAR THE WEST COAST OF INDIA DURING THE SOUTHWEST MONSOON,
Bhabha Atomic Research Centre, Bombay (India). Air Monitoring Section.
S. Sadasivan.
Atmospheric Environment, Vol 14, No 1, p 33-38, January, 1980. 3 Fig, 3 Tab, 27 Ref.

Descriptors: *Clouds, *Aerosols, *Rain, Precipitation, Seawater *India, *Trace levels, Halogens, Sulfates, Iodine, Bromine, Chlorides, Salts, Monsoons, Fallout, Chemical reactions.

Trace constituents were determined in cloud water, rain water, and impactor aerosol samples collected at a mountain top near the west coast of India during the summer monsoon in order to study the evolution of clouds and raindrops. Concentrations of trace constituents in cloud water were within the ranges previously reported for oceanic cloud water. Ratios of Cl, Br, and I to Na were close to those of seawater, indicating no incorporation of halogens in the cloud water. In cloud water there were excesses of Ca (probably from soil particles), K (from enrichment during transfer from seawater to air), and sulfates. Rainwater samples were difficult to analyze because the concentrations of trace constituents were near the detection limit. Average ammonium/sulfate ratio was 0.2; Cl and Na correlated well; and Br/Na and I/Na values were higher than samples from the coast taken previously. Aerosol particles collected under rainy conditions and clear weather conditions showed enrichment of Br and I at higher altitudes. These findings indicate that cloud droplets form on large and giant aerosol particles. There is no significant gaseous I absorption in raindrops. The aerosol composition explains the observed I enrichment in rainwater. (Cassar-FRC)

ON AUGUST MEAN TEMPERATURE AND THE SUCCEEDING SEASON'S RAINFALL OVER SOUTH AFRICA,
University of the Witwatersrand, Johannesburg (South Africa).
T. G. J. Dyer.
South African Journal of Science, Vol 76, No 2, p 85-87, February, 1980. 7 Fig, 1 Ref.

Descriptors: *Rainfall distribution, *Temperature control, *South Africa, Temperature, *Seasonal distribution, Precipitation, Model studies.

The relationship between August mean temperature and the total rainfall received during the following season was investigated in light of the commonly assumed interrelationship between the two factors. The study reveals that there may be some truth in the claim of an association between August mean temperature and rainfall over part of the rainy season. The correlation fields for November and December, and also for the whole season, have areas of significant coefficients. The whole-season correlation arises, however, by virtue of the form of the fields in the former two months and to a lesser extent of that which exists during January. This is based on the fact that the fields tend to weaken in an organized fashion as the season progresses. If there is a true relationship, it is highly spatially dependent, as no correlation exists to the north of a line through Bloemfontein and Durban. Even in the strongest fields the relationship accounts for only a relatively small proportion of the total relative variance in rainfall. However, these fields lend themselves to being considered as possible inputs to any model designed to forecast seasonal rainfall. (Baker-FRC)

A NUMERICAL COMPARISON BETWEEN LAGRANGIAN AND EULERIAN RAINFALL STATISTICS,
Stockholm Univ. (Sweden). Arrhenius Lab.
M. Hamrud, H. Rodhe, and J. Grandell.
Tellus, Vol 33, No 3, p 235-241, June, 1981. 2 Fig, 2 Tab, 10 Ref.

Descriptors: *Numerical analysis, *Precipitation, *Comparison studies, Mathematical studies, Rainfall, Precipitation scavenging, Statistical methods.

The problem of estimating statistical parameters characterizing the precipitation experienced by a parcel of air as it is carried along by the winds is of considerable interest in connection with studies of the transport and dispersion of air pollutants subject to precipitation scavenging. Lagrangian data are data relating to the 'weather' experienced by the air parcel as it is carried along by the wind. Eulerian data are meteorological observations obtained at fixed locations. This study investigated the relationship between Lagrangian and Eulerian rainfall statistics. Parameters characterizing Lagrangian precipitation statistics were derived using 850-mbar air trajectories over nothern Europe in conjunction with precipitation data. Comparisons with similar Eulerian statistics which had been spatially averaged over the area indicated that the magnitudes of these parameters differed only moderately between the two frames of reference. It therefore seems reasonable to assume as a first approximation an equality between the Lagrangian and the Eulerian estimates of the parameters studied. (Carroll-FRC)

RELATION OF SATELLITE-BASED THUNDERSTORM INTENSITY TO RADAR-ESTIMATED RAINFALL,
National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center.
A. J. Negri, and R. F. Adler.
Journal of Applied Meteorology, Vol 20, No 3, p 388-300, March, 1981. 9 Fig, 16 Ref.

Descriptors: *Thunderstorms, *Satellite technology, *Radar, *Weather forecasting, Correlation analysis, Storms, Remote sensing.

Measurements of thunderstorm intensity determined from short-interval geosynchronous digital satellite data were compared to precipitation measurements from radar data. In the satellite infrared data, the thunderstorms were defined by the location of the relative minima in the equivalent blackbody temperature field. When the evolution of a number of storms was examined, the first low level radar echo (18dBZ) appeared when the satellite observed cloud-top minimum blackbody temperature had a mean of 245 K (7.4 km). Larger reflectivities appeared as the cloud tops penetrated upward to colder temperatures. As the storms approached and penetrated the tropopause, reflectivity values greater than 50 dBZ began. A correlation was found between satellite-based estimates of thunderstorms and maximum radar reflectivity. Thunderstorm top ascent rates in the 235-240 K region indicated the intensity of the initial storm updraft and were correlated with the maximum storm reflectivity, with weak cells having minimum reflectivity and strong cells having echos equal to or greater than 50 dBZ. APPARATUS FOR THE SIMULATION OF RAIN IN THE LABORATORY,
State Univ. of New York at Albany.
D. R. Derenzo, and B. Vonnegut.
Journal of Applied Meteorology, Vol 20, No 1, p 36-41, January, 1981. 7 Fig, 1 Tab, 15 Ref.

Descriptors: *Rainfall simulators, *Simulated rainfall, *Calibrations, Rainfall, Laboratory equipment.

A method is described to produce simulated rain which does not require several meters of fall. The short fall distance means that the simulated rain can be produced without the aid of a rainshaft and within the convenience of normal ceiling height. A jet of water is directed toward the periphery of an automobile tire that rotates opposite to the flow of water. The rotating tire creates air and mechanical turbulence that break the jet up into a spray of water. Three rains having rainfall rates of 14, 48, and 2100 mm/hr were investigated using the simulator. The rains had drop-size distributions that exhibited characteristics of those found in natural rains. Also, drops fell at approximately terminal velocity. The apparatus can be used to calibrate meteorological instruments that measure some aspect of rainfall either in the field or laboratory. Examples of instruments would be those dealing with water drop-soil interactions. (Small-FRC)

SATELLITE RAIN ESTIMATION IN THE U.S. HIGH PLAINS,
National Oceanic and Atmospheric Administration, Boulder, CO.
C. G. Griffith, J. A. Augustine, and W. L. Woodley.
Journal of Applied Meteorology, Vol 20, No 1, p 53-66, January, 1981, 10 Fig, 10 Ref.

Descriptors: *Computer models, *Satellite technology, *Rainfall, Arid climates, Clouds, Error analysis, Weather forecasting, High plains, Remote sensing.

A computer-automated technique to estimate rainfall using visible or infrared geosynchronous satellite imagery was used to estimate rainfall on 15 selected days in the High Plains. Each site was instrumented with a small, dense raingage network to provide a ground measure of rainfall for verification. Model results exceeded the corresponding gage estimates by a factor of 3-5 because the model treated convective clouds in arid regions as tropical clouds. The technique was adjusted to apply to the High Plains. Gage and satellite comparisons were made for a small area, and this comparison was extrapolated to satellite rain estimates for large areas. A second adjustment technique involved calculation of an adjustment factor using the output of a one-dimensional cumulus cloud model. Preliminary results indicated that these adjusted techniques have considerable utility. The accuracy of the model is discussed in terms of bias, mean error factor, root mean square error, and linear regression analysis. (Small-FRC)

EVALUATION OF AREAL VERSUS POINT RAINFALL WITH SPARSE DATA,
Ecole Polytechnique, Montreal (Quebec). Dept. of Civil Engineering.
V-T-V. Nguyen, J. Rousselle, and M. B. McPherson.
Canadian Journal of Civil Engineering, Vol 8, No 2, p 173-178, June, 1981. 10 Fig, 1 Tab, 11 Ref.

Descriptors: *Areal precipitation, *Rainfall distribution, *Mathematical studies, Mathematical models, Precipitation, Hydrology, Geography, Probabilistic process, Mathematical equations, *Urban hydrology, *Rainfall-runoff relationships, *Runoff forecasting.

Urban hydrologic studies designed to determine runoff peaks and volumes depend on both temporal and spatial information on rainfall distribution. Since rainfall data used as input to rainfall-runoff models are measured at a point, it is necessary to establish some relationships for the transformation of point rainfall data to areal rainfall. Mean rainfalls for a fixed area and the associated rainfall for a fixed point in that area were analyzed from a probabilistic perspective, and a theoretical methodology for establishing a relationship between these values is proposed. An exponential distribution function for hourly point rainfall was used to derive the distribution relation for mean rainfall over a fixed geographic area. Values of the areal correction factor were estimated at equal levels of exceedance probability for point and areal mean rainfalls. These estimations showed that the areal correction factor is not constant for all return periods and that its value may not always be less than or equal to 1. The point-areal rainfall relationship developed by this study may be more realistic and more useful for many engineering applications because in nature the occurrence of storm centers in a given region is thought to be purely random and in engineering practice attention is often focussed on a fixed area. (Carroll-FRC)

ASSOCIATIONS AND MESOSCALE SPATIAL RELATIONSHIPS AMONG RAINWATER CONSTITUENTS,
Illinois State Water Survey, Urbana.
D. F. Gatz.
Journal of Geophysical Research, Vol. 85, No C10, p 5588-5598, October, 1980. 3 Fig, 13 Tab, 12 Ref.

Descriptors: *Chemistry of precipitation, *Deposition, *Factor analysis, Rainwater, Mathematical studies, Precipitation, Scavenging, Metals, Heavy metals, Sulfates, Air pollution effects.

Information about how rainwater constituents are scavenged from the atmosphere and precipitated was collected in a study of 10 rain events near St. Louis during the summers of 1972-1975. Factor analysis was used to identify groups of constituents having similar deposition patterns. Rainwater samples were collected in networks of 80 or 85 open polyethylene containers and were analyzed for Li, Na, Mg, K, Ca, Fe, Zn, Cd, In, Pb, and sulfate. Four main groupings of depositional patterns occurred: soluble soil-derived elements, insoluble soil-derived elements, soluble pollutants, and insoluble pollutants. Differences between the depositional patterns of pollutants and soil elements are probably due to the distribution of sources. The differences between soluble and insoluble portions of the same element may indicate important differences in scavenging and/or precipitation formation processes. These processes need further investigation. (Small-FRC)

SULFUR AND ASSOCIATED ELEMENTS AND ACIDITY IN CONTINENTAL AND MARINE RAIN FROM NORTH FLORIDA,
Florida State Univ., Tallahassee. Dept. of Oceanography.
S. Tanaka, M. Darzi, and J. W. Winchester.
Journal of Geophysical Research, Vol 85, No C8, p 4519-4526, August, 1980. 5 Fig, 4 tab, 15 Ref.

Descriptors: *Acid rain, *Sulfur, *Rainfall, *Chemical composition, Water analysis, Metals, Air pollution effects, North Florida, Baseline studies, Environmental surveys, *Florida.

The composition characteristics of north Florida rain were investivated to establish some nonurban baselines of elemental concentrations and to estimate the extent of transport of air pollutants. A new measuring technique was used, the proton-induced X-ray emission (Pixe), which could analyze a wide range of elements from S to Pb simultaneously. Elemental composition was determined for: S, K, Ca, V, Mn, Fe, Ni, Cu, Zn, Br, Sr, and Pb, from 4 ml aliquots of 38 different rain samples. Northerly air flow rain exhibited polluted and continental characteristics. Concentrations of Pb, S, and Fe were higher, and strong correlations of Br, Ca, and Fe with Pb were found. In general, southerly air flow rain had lower elemental concentrations, and element concentrations were not correlated with Pb. The average pH of northern rain was 4.4, while southern rain had an average pH of 5.3. The region of influence for atmospheric pollution industrial regions seemed larger than is usually thought. THE MAGNITUDE OF THE HYDROLOGICAL FREQUENCY FACTOR IN MAXIMUM RAINFALL ESTIMATION,
Science and Education, Beltsville, MD. Hydrology.
D. M. Hershfield.
Hydrological Sciences Bulletin, Vol 26, No 2, p 171-177, June, 1981. 5 Fig, 1 Tab, 7 Ref.

Descriptors: *Rainfall, *Probable maximum precipitation, *Frequency analysis, Precipitation, Probability distribution, Mathematical studies, *Eastern United States.

Results from several sets of maximum rainfall data are compared and related in terms of a frequency factor. Chow's hydrological frequency factor is used, which is primarily a function of the recurrence interval for a particular probability distribution. This frequency factor is displayed as a function of the mean of the annual maxima for both official and unofficial rainfall observations and the probable maximum precipitation. The frequency factor is shown to be a function of the magnitude of the unofficial rainfall observations and probable maximum precipitation for areas in the eastern U.S. This suggests that the magnitude of probable maximum precipitation is largely influenced by the magnitude of the frequency factor. The geographical distribution of the probable maximum distribution factor was displayed on maps for the eastern United States, and ranged from about 20 in the south to more than 35 in the north. NUMERICAL SIMULATION OF THE EFFECTS OF COOLING TOWER COMPLEXES ON CLOUDS AND SEVERE STORMS,
South Dakota School of Mines and Technology, Rapid City.
H. D. Orville, P. A. Eckhoff, J. E. Peak, J. H. Hirsch, and F. J. Kopp.
Atmospheric Environment, Vol 15, No 5, p 823-836, 1981. 12 Fig, 1 Tab, 24 Ref.

Descriptors: *Cooling towers, *Storms, Rainstorms, Hail, Rain, *Temperature effects, Simulation analysis, Mathematical studies, Model studies, *Powerplants, Heat, Clouds, Latent heat, Sensible heat.

Attempts were made to determine the effects of excess heat and vapor from large power parks on heavy rain and hailstorms through the use of numerical simulation studies. A two-dimensional, time-dependent model was used which gave realistic simulations of many severe storm processes

including heavy rains, hail and strong winds. The model is a set of partial differential equations which describe time changes of momentum, energy, and mass. Appropriate boundary and initial conditions are imposed on a domain about 20 km high by 20 km wide and 200 meter grid intervals to complete the model. Modifications were made to allow additional water vapor and heat to be added at several lower grid points to simulate effluents from a power peak. Realistic storm situations were recreated. One atmospheric sounding has a strong middle-level inversion which tends to inhibit the first convective clouds but later gives rise to a severe storm with hail and heavy rains. One other sounding is taken from a day in which a severe storm occurred in the Miami area. A third sounding depicts atmospheric conditions in which severe storms formed in the vicinity of Huron, South Dakota. Results of the study indicate that a power park emitting 80% latent heat and 20% sensible heat has little effect on the simulated storm. A case with 100% sensible heat emission leads to a much different solution, with the simulated storm reduced in severity and the rain and hail redistributed. A case in which water vapor is accumulated in a region and released over a broad depth results in slightly more rain from a severe storm. (Baker-FRC)

VARIATIONS IN PRECIPITATION PARAMETERS BETWEEN DROUGHT AND NON-DROUGHT PERIODS IN TEXAS AND SOME IMPLICATIONS FOR CLOUD SEEDING,
National Weather Service Stoneville, MS.
M. S. Flynn, and J. F. Griffiths.
Journal of Applied Meteorology, Vol 19, No 12, p 1363-1370, December, 1980. 1 Fig, 6 Tab, 3 Ref.

Descriptors: *Drought, *Cloud seeding, Weather modification, Moisture deficiency, Water shortage, Water deficit, Artificial precipitation, Rainfall, Irrigation practices, *Texas.

Information concerning rainfall patterns over Texas was extracted from the Texas Section of Hourly Precipitation Data of the US Weather Bureau, 1950-1973. The data involved a study of hourly rainfall for the period of time used for the current study, 1950-1969. Twelve key sites were selected for the evaluation. No easily identifiable patterns for regions emerged from the analysis of the data, which may indicate that many more than 12 sites should be included in future studies. Based on these stations, however, severe droughts in Texas appeared to be characterized by a reduction in both the number of individual rainfalls experienced and a reduction in the intensity of the falls. This indicates that days of cloud seeding opportunity as well as natural precipitation efficiency are diminished, and attempts to start rainfall by artificial methods may have limited success. Length of rainfall during severe droughts is also diminished significantly, and therefore there would be little opportunity for seeding clouds already producing rain. It is also suggested that there is a little benefit to be gained by shutting down irrigation equipment once a rain has started during a severe drought. (Baker-FRC)

PHYSICAL MECHANICS OF AUFEIS GROWTH,
Alaska Univ., Fairbanks. Inst. of Water Resources.
D. L. Kane.
Canadian Journal of Civil Engineering, Vol 8, No 2, p 186-195, June, 1981. 9 Fig, 21 Ref.

Descriptors: *Aufeis, *Freezing, *Arctic, Polar regions, *Ice formation, Physical properties, River mechanics, Pore pressure, Water pressure, Groundwater, Permafrost, Frozen ground, Piezometers, Time series analysis, Mathematical studies, Alaska.

Although subsurface physical systems in arctic and subarctic regions are frequently considered to be dormant during the winter months, several heat and mass transfer processes near the surface are quite active. These include aufeis growth, which occurs when water under pressure in a stream channel flows onto the existing ice cover and freezes. Data relating to the process of aufeis growth were collected on two small watersheds near Fairbanks, Alaska, over several winters. The pressure variations of the fluid in the porous streambank were measured using piezometers installed at several sites. Time series analyses were used to correlate the variations in the observed pore pressures with climatic variables. The piezometer measurements of pore water pressure indicated that subpermafrost groundwater or groundwater from nonpermafrost regions was the source of water for these ice deposits. Groundwater pore pressures were found to be sufficient to vertically lift the soil overburden and ice in the vicinity of the stream if an impermeable barrier existed. Ice lenses, formed when the seasonal frost penetrated to a zone high in soil moisture, provided this barrier. Ice wedges were found to develop in the seasonal frost zone near the water table, and the thickness of this ice wedge decreased with increasing distance from the stream. Time series analysis of air temperature and groundwater pore pressure indicated that periods of aufeis growth would be associated with or follow periods of moderately warm weather. Although the raw data for the later winter months supported this conclusion, it was less evident in the early winter months. A time lag was also found to exist between the start of a warming trend and the corresponding increase in pore water pressure, and this time lag increased with increasing ice thickness. (Carroll-FRC)

OCCURRENCE OF ICE LAYERS AT THE BASE OF HIGH ARCTIC SNOWPACKS,
McMaster Univ., Hamilton (Ontario). Dept. of Geography.
M-K. Woo, and R. Heron.
Arctic and Alpine Research, Vol. 13, No. 2, p 225-230, May 1981. 3 Fig, 1 Tab, 6 Ref.

Descriptors: *Snowpack, *Ice formation, Cold regions, *Arctic zone, Snowmelt, Melting, Interfaces, *Canada, Cornvallis Island.

Field observations were carried out near Resolute, Cornwallis Island, North West Territory, during the snowmelt periods of 1979 and 1980 at sites underlain by gravel, bog, and lake ice wich was frozen to the lake bottom. At each site, snow temperatures and temperatures at various depths in the ground or in the lake ice were measured using thermistors. The measurements suggest two stages in the formation of a basal ice layer in most High Arctic snowpacks, including seepage of the meltwater into the frozen substrate before the ice is formed and initiation and sustained growth of a basal ice layer. Each stage of development seems to be affected by a set of conditions which can terminate further ice growth. At the seepage stage, the amount of meltwater lost to the substrate depends on the nature of the frozen material and the amount of ice already frozen in its pores. Seepage loss to lake ice is negligible because of its low permeability, but the ample pore space in coarse gravel will permit substantial seepage, and basal ice layer formation may be retarded. When most pores in the frozen substrate are sealed, further supplies from the pack will freeze as a basal ice layer if the substrate is sufficiently cold to dissipate the latent heat. With warming, however, additional meltwater will slush the snow above the ice layer, or will move downslope along the ice surface. A collection of lateral drainage sometimes produces thick ice layers in topographic depressions, as long as the ground temperature remains below zero degrees centigrade for an extended time. (Baker-FRC)

THE EFFECTS OF SURFACE DUST ON SNOWMELT RATES,
McMaster Univ., Hamilton (Ontario). Dept. of Geography.
J. J. Drake.
Arctic and Alpine Research, Vol. 13, No 2, p 219-223, May, 1981. 1 Fig, 14 Ref.

Descriptors: *Snowmelt, *Dusts, Wind velocity, solar radiation, Mathematical studies, Mathematical models, Temperature effects, Snowpack.

A basic assessment is presented of both the albedo and other effects of surface dust on snowmelt rates. These effects are illustrated with a particular numerical example from Schefferville. A model is presented which demonstrates the changes in albedo and surface temperature in relation to dust cover. This model leads to realistic order-of-magnitude estimates of the conditions under which snowmelt will be advanced or retarded. Thick dust covers, low solar radiation and high windspeeds retard snowmelt, while thin dust covers, intense solar radiation and low windspeeds increase snowmelt rates. The results agree with an earlier observation that dust covered snow near active mine sites is completely melted some four days before the general snowpack in the area. Other experiments have demonstrated that Mount St. Helens ash retards melt at thickness greater than 10 to 20 mm. (Baker-FRC)

THE DISTRIBUTION OF SEA ICE MELTWATER IN THE EASTERN CANADIAN ARCTIC,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia). Atlantic Oceanographic Lab.
F. C. Tan, and P. M. Strain.
Journal of Geophysical Research, Vol 85, No C4, p 1925-1932, April, 1980. 11 Fig, 3 Tab, 24 Ref.

Descriptors: *Isotopic tracers, *Sea ice, Snowmelt, *Arctic zone, Isotope studies, Salinity, *Baffin Bay, *Canada, Melt water.

The feasibility of using oxygen isotope techniques to study the formation of Baffin Bay (eastern Canadian Arctic) bottom water was investigated. Water samples and sea ice cores were collected and analyzed to determine the oxygen isotopic composition. The nature of freezing seawater is such that sea ice contains much less salt than the water from which it was formed but does not have a very different isotopic composition. The distribution of sea ice melt water in the area was determined. Results indicated that the proposal by Sverdrup et al. which suggests that this water mass is a mixture of Labrador Sea deep water and Baffin Bay surface waters may be true. The analysis also gave support to the formation mechanism proposed by Collin and Bailey. Greater than 250-m water in Nares Strait (Smith Sound) had the same isotopic composition as both Baffin Bay deep water and bottom water. The difference in salinity between the Nares Strait water and the bottom water could be due to the addition of brines during ice formation. (Small-FRC)

SEASONAL CHANGES IN LEAF AREA, STOMATAL AND CANOPY CONDUCTANCES AND TRANSPIRATION FROM BRACKEN BELOW A FOREST CANOPY,
Institute of Hydrology, Wallingford (England).
J. Roberts, C. F. Pymar, J. S. Wallace, and R. M. Pitman.
Journal of Applied Ecology, Vol 17, No 2, p 409-422, August, 1980. 5 Fig, 5 Tab, 22 Ref.

Group 2D—Evaporation and Transpiration

Descriptors: *Stomatal transpiration, *Forests, *Canopy, Leaves, Conductance, Pine trees, Trees, Evapotranspiration, Seasonal variation, Water consumption.

The use of water by forests depends both on the major tree species present and on the amount and type of undercover. Therefore, in studying the factors controlling evaporation from a Scots pine forest at Thetford Chase, East Anglia, it was necessary to estimate the contribution from the bracken undergrowth. The development of the bracken canopy beneath the forest was investigated and the values of stomatal and canopy conductances were obtained for use in calculating bracken transpiration. Transpiration from the bracken was calculated using leaf area index and stomatal conductance values and appropriate environmental variables in the Penman-Monteith Equation. Calculated transpiration agreed well with independent values derived by weighing transplanted bracken. The contribution of bracken to the total forest transpiration was over 50% when the soil was driest and the atmospheric humidity deficits were also high. Under normal summer conditions, the bracken underbrush contributed between 20 and 25% of the total forest transpiration. Bracken stomatal conductance appears to be largely insensitive to atmospheric humidity deficits or to soil moisture conditions in forest environments. (Carroll-FRC)

CONSUMPTIVE USE AND DAILY EVAPOTRANSPIRATION OF CORN UNDER DIFFERENT LEVELS OF NITROGEN AND MOISTURE REGIMES,
Andhra Pradesh Agricultural Univ., Hyderabad (India). Dept. of Agronomy.
M. Devender Reddy, I. Krishna Murthy, K. Anand Reddy, and A. Venkatachari.
Plant and Soil, Vol 56, No 1, p 143-147, 1980. 3 Fig, 6 Ref.

Descriptors: *Corn, *Evapotranspiration, *Consumptive use, Water use, Nitrogen, Crop yield, Semiarid lands, Fertilization, Soil water, *India, Soil-water-plant relationships.

Cropping of corn in the semi-arid regions of Andhra Pradesh, India, was investigated by determining corn's seasonal consumptive use, daily evapotranspiration, and water use under different levels of nitrogen and moitsure regimes. Consumptive use difference was less among different nitrogen levels, but was marked between different moisture regimes. Evapotranspiration was less in the initial stages of the growing season, attained a peak at 80% of the growing season, and declined at the end of the season when maturity was reached. As nitrogen levels increased up to 180 kg N/ha, water use efficiency increased. There was a close relationship between the continuous availability of soil moisture and the response of corn to fertilizer application. If soil moisture becomes a limiting factor, the addition of fertilizer at this time might adversely affect the yield. Among moisture regimes, higher water use efficiency was found under 20% available soil moisture depletion. (Small-FRC)

THE INFLUENCE OF PLANT COMMUNITIES UPON THE HYDROLOGY OF CATCHMENTS,
Flinders Univ. of South Australia, Bedford Park. School of Earth Sciences.
J. W. Holmes, and E. B. Wronski.
Agricultural Water Management, Vol 4, No 1-3, p 19-34, 1981. 2 Fig, 8 Tab, 27 Ref.

Descriptors: *Catchment areas, *Vegetation effects, *Evapotranspiration, *Forest watersheds, Evaporation rate, Leaves, Runoff, Groundwater recharge, Hydrology, *Australia.

The effect of land use on the water yield from catchments is reviewed, with emphasis on forested land. In general, less runoff occurs on forested catchments because the evapotranspiration from them is larger than from catchments not in forest. Rainwater held upon wet foliage evaporates faster than the transpiration rate would be if the leaves were dry. Interception loss may account for the observed yields from forested catchments, up to 200 mm/yr less than, for example, grassland. The interception store can be 2 mm. Also, deep-rooted perennial plants created a soil-water deficit that is probably larger than that caused by annual pastures or cereal crops. The data available indicate that it is probable that a soil-water deficit of 250 mm each year could be created by an evergreen forest and 180 mm each year by annuals. This is valid for the climatic regions of southern Australia, where rainfall is 700 mm/year or more. This implies a yield of 70 mm/year less from forested land in runoff or recharge of groundwater. Thus, a forested area will experience enhanced evaporation of rainwater on leaves, and this may eventually cause hydrologic changes. (Small-FRC)

LEAF AND ENVIRONMENTAL PARAMETERS INFLUENCING TRANSPIRATION: THEORY AND FIELD MEASUREMENTS,
Wyoming Univ., Laramie. Dept. of Botany.
W. K. Smith, and G. N. Geller.
Oecologia, Vol 46, No 3, p 308-313, September, 1980. 3 Fig, 1 Tab, 21 Ref.

Descriptors: *Desert plants, *Leaves, *Transpiration, Xerophytes, Stomatal transpiration, Soil-water-plant relationships.

This paper investigated the influence of changes in leaf size or wind on transpiration at a given stomatal resistance for various combinations of air temperature and absorbed solar energy. Predicted transpiration either increased or decreased for increases in leaf size depending on the specific combinations of the above factors. Major reductions in simulated transpiration with increasing leaf size occurred for shaded, highly reflective, or specially oriented leaves (fraction of full sunlight, 0.1) at relatively high air temperatures when stomatal resistance was below 500 s per m. Increases in fraction of sunlight (to 0.7) and decreases in air temperature (to 20 C) lowered this critical resistance to below 50 s per m. When stomatal resistance was above this critical value of 500 s per m, transpiration increased with larger leaves and less wind. The theoretical results were compared to field measurements on some desert plants. (Cassar-FRC)

SOIL MOISTURE RELATIONS IN THE SOUTHERN CALIFORNIA CHAPARRAL,
San Diego State Univ., CA. Dept. of Biology.
E. Ng, and P. C. Miller.
Ecology, Vol 61, No 1, p 98-107, 1980. 6 Fig, 3 Tab, 53 Ref.

Descriptors: *Soil moisture, *Chaparral, *California, Drought, Moisture availability, Transpiration, Vegetation regrowth, *Soil-water-plant relationships.

Soil moisture balance and vegetation studies were conducted on two chaparral-covered slopes in southern California. Vegetation on the north-facing slope was dominated by Ceanothus greggii, and on the south-facing slope by Adenostoma fasciculatum. Vegetation cover on the north-facing slope was greater than on the south-facing slope. Throughout the year, soil moisture at 0.3-1.0 m depths was greater on the south-facing slope than on the north-facing slope. Soil texture on the two slopes did not differ significantly. Precipitation on the two slopes was the same, averaging 30 cm/year, below the usual level for this area. Subsurface drainage was greater on the south-facing slope and peaked in January, close to the time of maximum precipitation. Evaporation was greater on the south-facing slope, but transpiration was greater on the north-facing slope. The greater vegetation cover and drier soils on the north-facing slope are probably related to the drought-resistant nature of vegetation in this mediterranean climate. The greater transpiration on the north-facing slope is probably due to the ability of the plants on this slope to draw water from deeper soil layers and to maintain open stomata at lower water potentials. This paper provides the crop coefficient of early potatoes, corn and processing tomatoes using evapotranspiration data on irrigated crops collected from floating lysimeters and potential crop evapotranspiration obtained from Class A pan at Harrow for the growing season of 1963 through 1972. The crop coefficient is the ratio of crop evapotranspiration to potential or maximum evapotranspiration. The value of the crop coefficient depends on the percentage of foliage cover on the soil, increasing from emergence to about 50-80% of foliage cover, remaining at a maximum value for about 2-5 weeks, and thereafter decreasing during the late season stage until the crops approach maturity. The low value of the crop coefficient at the initial stage of crop development may be attributable to the evaporation rate from bare soil. The soil evaporation can be affected by irrigation and rainfall frequency. As the soil surface water dries out, though the root zone water is ample, the value of the crop coefficient will remain at a low value. This is because the capillary flow from the root zone of the soil body to the soil surface limits the rate of evaporation. As the percentage of foliage cover continues to increase, the evaporation from soil becomes less important and remains relatively constant. (Baker-FRC)

A LEAKY RESERVOIR MODEL FOR EPHEMERAL FLOW RECESSION,
Office of Surface Mining Reclamation and Enforcement (DI), Washington, DC.
R. W. Peebles, R. E. Smith, and S. J. Yakowitz.
Water Resources Research, Vol 17, No 3, p 628-636, June, 1981. 9 Fig, 1 Tab, 12 Ref.

Descriptors: *Ephemeral streams, *Recession, *Streamflow forecasting, Reservoirs, Storage, Flood flow, Flood peak, *Model studies, Hydrographs, Infiltration, Reservoir leakage, *Streamflow depletion.

A leaky reservoir model is proposed to represent streamflow recession in an ephemeral stream. The model is described by a continuity equation, a discharge-stage relation (stream rating), and a stage-storage relation (reservoir configuration). The infiltration loss in the stream channel is analogous to leaking in the bottom of a reservoir. No input is routed through the reservoir: at the onset of the recession the reservoir has water in storage. By calibrating reservoir leakage rate and initial storage (reservoir shape) a good fit to observed curves is obtained. The most critical parameter is reservoir shape; recession curves do not change much with changing reservoir loss rate. (Cassar-FRC)

EFFECTS OF RECENT INCREASES IN RAINFALL ON FLOODS AND RUNOFF IN THE UPPER HUNTER VALLEY,

New South Wales Univ., Kensington (Australia). School of Geography.
F. C. Bell, and W. D. Erskine.
Search, Vol 12, No 3/4, p 82-83, March/April, 1981. 2 Fig, 1 Tab, 8 Ref.

Descriptors: *Runoff, *Flood frequency, Channel improvement, *Rainfall-runoff relationships, *Hunter Valley, *Australia, Streamflow, Water resources development.

Recent large and significant changes in flood frequencies and annual runoff were observed since 1946 in the Hunter Valley, Australia. Results of analysis of rainfall and runoff records since 1898 suggest that the cause is the increased rainfall and lower frequency of dry years after 1946, not catchment modifications or disturbance. Before 1946, channel and catchment modifications probably caused decreases in runoff and runoff variability during dry years and increases during wet years. After 1946 there was no effect from modification activities. (Cassar-FRC)

Descriptors: *Floods, *Flood data, *Flood damage, *Flood peak, *Flood profiles, Gaging stations, Flood flow, Streamflow, Rainfall-runoff relationships, Flood frequency, Hydrologic data, Flood hydrographs, *Missouri, *Kansas, *Kansas City.

The storms of Sept. 12-13, 1977, delivered as much as 16 in. of rain, with average rainfall exceeding 10 in. in the Kansas City metropolitan area. Twenty-five lives were lost, many were left homeless, and damages exceeded $80 million. Data obtained by the National Weather Service and the U.S. Geological Survey indicate that two record-setting rainstorms occurred within 24 hours. The first storm, in the early morning, thoroughly soaked the local drainage basins. The second storm, centered along the Brush and Round Grove Creek basins, resulted in a devastating flash flood. Peak discharges were determined during and after this major flood at gaging stations and selected miscellaneous locations. Streamflows and flood volumes in many locations far exceeded estimated values for the 100-year flood. (USGS)

H. E. Jobson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-225757, Price codes: A09 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-2, 1980. 165 p, 21 Fig, 2 Tab, 24 Ref.

Descriptors: *Computer models, *Temperature, *Solute transport, *Streamflow, Path of pollutants, Tracking techniques, Traveltime, Rivers, Flow, Unsteady flow, Open channels, Numerical analysis, Mathematical models, Prediction, Computer programs.

A computer program for simulating one-dimensional, unsteady temperature and solute transport in a river has been developed and documented for general use. The solution approach to the convective-diffusion equation uses a moving reference frame (Lagrangian) which greatly simplifies the mathematics of the solution procedure and dramatically reduces errors caused by numerical dispersion. The model documentation is presented as a series of four programs of increasing complexity. The conservative transport model can be used to route a single conservative substance. The simplified temperature model is used to predict water temperature in rivers when only temperature and windspeed data are available. The complete temperature model is highly accurate but requires rather complete meteorological data. Finally, the 10-parameter model can be used to route as many as 10 interacting constituents through a river reach. (USGS)

THE ROLE OF SUBSTRATUM IN BENTHIC MACROINVERTEBRATE MICRODISTRIBUTION AND LITTER DECOMPOSITION IN A WOODLAND STREAM,
North Carolina Univ. at Chapel Hill. Dept. of Zoology.
S. R. Reice.
Ecology, Vol 61, No 3, p 580-590, 1980. 4 Fig, 5 Tab, 38 Ref.

Descriptors: *Ecosystems, *Streams, Litter, Organic matter, *Leaves, *Decomposition, Decomposing organic matter, Detritus, *Macroinvertebrates, Spatial distribution, *Substrates, New Hope Creek, Orange County, *North Carolina, Forest watersheds.

The contribution of substratum per se on decomposition of leaf litter and microdistribution of benthic invertebrates in streams were investigated. The study was conducted in winter 1975-76 in New Hope Creek, Orange County, North Carolina. The site was Duke Forest, which affords a protected habitat. The substratum was relatively uniform, consisting of cobbles with a few boulders, some sand, and gravel. Overall litter decomposition did not vary among substrata. The fraction of animal populations in leaf packs was proportional to the biomass remaining. Animals showed substratum preferences even when velocity differences were eliminated. Preferences of common taxa were unaffected by the presence or absence of leaf packs on the substratum. Common taxa showed strong preferences for either leaves or substrata. Abundance data strongly contradict the density data. The latter measure offers more biological insight. These results emphasize the importance of substratum size as a prime determinant of the structure of lotic macroinvertebrate communities. (Baker-FRC)

A MATHEMATICAL MODEL FOR CONSOLIDATION IN A THERMOELASTIC AQUIFER DUE TO HOT WATER INJECTION OR PUMPING,
Michigan Univ., Ann Arbor. Dept. of Civil Engineering.
J. Bear, and M. Y. Corapcioglu.
Water Resources Research, Vol 17, No 3, p 723-736, June, 1981. 1 Fig, 30 Ref.

Descriptors: *Subsidence, *Geothermal studies, Aquifer management, *Mathematical models, Model studies, *Thermal water, *Injection wells, Wells, Pore pressure, Energy, Storage.

This paper develops a mathematical model to estimate fluid pressure, temperature, land subsidence and horizontal displacement produced by hot water injection into thermoelastic confined and leaky aquifers (for energy storage), pumping from a geothermal field, or flooding a warm aquifer with cold water. Assuming that the aquifer is thin relative to the horizontal distances involved, the dependent variables are average (over the aquifer thickness) values. The solid matrix is assumed to be thermoelastic. After development of three-dimensional conservation of mass and energy equations and equilibrium equations in terms of horizontal and vertical displacements, the model is derived by averaging the three-dimensional model over the vertical thickness of the aquifer, subject to conditions of plane total stress. The resulting averaged coupled equations are stated in terms of pore water pressure, temperature, and vertical and horizontal displacement. An example of a single pumping/injection well is given as an illustration. (Cassar-FRC)

Descriptors: Porosity, Thermodynamics, *Model studies, *Groundwater movement, Mathematical studies, Capillary water, *Porous media, Soil water, Capillary coductivity.

The objective of this work is to present a set of transport equations which incorporates most of the existing models by combining the mechanistic and irreversible thermodynamics approaches to heat and mass transfer in porous media. A comparison between the non-equilibrium thermodynamics equations and those obtained from a mechanistic reasoning leads to the evaluation of the phenomenological coefficients. DuFour and Soret's coefficients are obtained from Onsager's relationships. The model describes transport phenomena in capillary-porous media. It is shown based on the local equilibrium principle, that the isothermal driving force for both liquid and vapor transfer in a porous medium is the gradient of equilibrium moisture content. Thus, it is postulated that water, in a capillary-porous medium, can move in opposition to a moisture content gradient, but always in the direction of the equilibrium moisture content gradient. Results from the resistivity method for locating a fresh-salt water interface agreed with known hydrologic data. The study site was the west-central Gulf coast area of Florida, where 28 vertical electrical soundings were done. Four geoelectric layers were revealed: surficial sands; a karstic, highly transmissive carbonate; a less porous carbonate; and a saline carbonate layer with resistivity of less than 1 ohm-meter. The depth of the fresh-salt water interface decreased toward the coast. (Cassar-FRC)

Recent effects in refining mathematical techniques to describe aquifer characteristics are summarized. Ground water hydrologists are primarily concerned with the storage coefficient (S) and the coefficient of transmissivity (T). The latest advance is the work by Rushton, presented in 1978. A mathematical model was developed to estimate transmissivity and the storage coefficient from pumped well data only. In 1971 Nawrocki experimentally compared four methods of determining T and S. No method was found to yield consistently higher or lower results than the others. The sensitivity of the various equations to the accuracy of the data input had not been determined. The major factor limiting the accuracy of aquifer coefficients is the inhomogeneity of real aquifers. In the future, a good appreciation for the inherent variations in the coefficients should be combined with an awareness of the final use intended for the coefficients. (Small-FRC)

Descriptors: *Groundwater mining, *Mathematical models, *Glacial aquifers, Aquifers, Glaciers, Bedrock, *Wisconsin, Groundwater potential.

This study defined zones within valley fill in northeastern Wisconsin that have a high probability of containing high-yield drift aquifers. A depositional model was developed to aid in the location of high-yield drift aquifers. The yield and spatial distribution of glacial aquifers were controlled by bedrock topography and glacial geology. Driller's logs were used to obtain lithologic control for identification and classification of aquifer units. This information was combined with seismic refraction and gravity survey data to derive the bedrock elevation map. Bedrock topography strongly influenced the distribution and character of glacial units and clearly delineated two glacial aquifer types: valley and morainal units. Valley aquifers are the most productive. Using statistical analysis, a model was developed which allows the knowledge of bedrock topography to be coupled with glacial geology to predict the spatial distribution of glacial aquifers. HYDROGEOLOGY OF THE SIERRA NEVADA FOOTHILL LINEAMENT NEAR OAKHURST, CALIFORNIA,
California State Univ., Fresno. Dept. of Geology.
S. Mack, and K. D. Schmidt.
Ground Water, Vol 19, No 2, p 149-155, March/April, 1981. 5 Fig, 2 Tab, 11 Ref.

Descriptors: *Geologic history, *Groundwater, *Chlorides, Connate water, Granites, *Sierra Nevada, California, *Geohydrology.

The influence of hydrogeologic factors on the distribution of high chloride ground water is discussed for the Sierra Nevada Foothill lineament near Oakhurst, California. This northwest trending lineament extends for 60 miles along the western Sierra Nevada foothills of Fresno and Madera Counties and includes 33 wells and two springs. The high-chloride water was probably influenced by connate waters derived from the compaction of Paleozoic and early Mesozoic marine clastic rocks in the Sierra Nevada. If granitic plutons in the area are presumed to be fairly thin mushroom-like complexes emplaced in the upper crust, hydrologeologic relations are explained. Marine connate water migration upward more or less vertically from a fault zone beneath a capping of granitic rock defined the lineament. Excellent correlation was found in the Oakhurst Basin between air-photo linear features and wells yielding high-chloride water. The persistence of the high-chloride water may be due to the high density of the connate water and the lack of deep circulation of meteoric water beneath topographically low areas. (Small-FRC)

A COMBINATION OF ELECTRICAL RESISTIVITY, SEISMIC REFRACTION, AND GRAVITY MEASUREMENTS FOR GROUNDWATER EXPLORATION IN SUDAN,
Groundwater Survey TNO, Delft (Netherlands).
R. A. van Overmeeren.
Geophysics, Vol 46, No 9, p 1304-1313, September, 1981. 10 Fig, 10 Ref.

Descriptors: Water resources development, *Geophysics, *Groundwater potential, Seismology, Gravity studies, Resistivity, Bedrock, Salinity, Exploration, *Geohydrology, *Sudan.

An integrated application of several geophysical exploration methods provided hydrogeologic information during groundwater exploration in the Sudan. Electrical resistivity, seismic refraction, and gravity methods were used to study prospects for additional supply of groundwater. Multilayer electrical sounding curves were already available and an additional 16 vertical electrical soundings were made. Seismic refraction work was carried out at selected locations to yield additional information on depths to bedrock. Using seismic data, a unique solution was found for the electrical souding curves, from which it was concluded that groundwater in the area was saline. Drilling tests confirmed these findings. A regional relative Bouguer anomaly map gave a picture of the general geologic structures and estimated depths to bedrock. In areas such as this where the basement rocks are close to the surface, gravity anomalies cannot be corrected with bedrock relief because of the strong influence of lateral density variations within the bedrock. Reliable data on depth to bedrock and formation resistivities could not have been obtained using only one of the techniques. (Small-FRC)

A METHOD FOR ESTIMATING RECHARGE AND BOUNDARY FLUX FROM GROUNDWATER LEVEL OBSERVATIONS,
Institute of Hydrology, Wallingford (England).
P. J. Smith, and R. S. Wikramaratna.
Hydrological Sciences Bulletin, Vol 26, No 2, p 113-136, June, 1981. 11 Fig, 2 Tab, 16 Ref.

Descriptors: *Groundwater recharge, *Transmissivity, *Water level, Fluctuations, Mathematical studies, Estimating equations, Groundwater management, Semiarid lands.

A new method is proposed for the estimation of recharge and boundary flux based on water level and transmissivity observations. It is particularly useful in semiarid regions where a steady state formulation can be used and recharge is confined to certain known areas. When this inferred recharge method is applied to a typical problem, it is an improvement over the implied recharge method. The variances for inferred recharge are satisfactory estimates of those obtained in simulations. Even when these variance estimates are large, alternative hypotheses can be tested about the mechanism of recharge using statistical significance tests. An error in the transmissivity distribution has less effect than an error of the same proportion in the water level observations, which means that this method can be useful in the early stages of modelling studies when only crude assessments have been made. These early results can aid

in the design of a field data collection program. (Small-FRC)

WELL-FIELD DRAWDOWNS USING COUPLED AQUIFER MODEL,
Law Engineering Testing Co., Tampa, FL.
L. H. Motz.
Ground Water, Vol 19, No 2, p 172-179, March/April, 1981. 10 Fig, 6 Ref.

Descriptors: *Drawdown, *Aquifers, *Wells, Model studies, Groundwater movement, Water table aquifers, Pumping tests, Evapotranspiration, Jay B Starkey Wilderness Park, *Florida.

A coupled aquifer model (Motz, 1978) was used to investigate well field drawdowns in the Jay B. Starkey Wilderness Park, Pasco County, Florida. In this model, water pumped from an underlying artesian aquifer originates from leakage through an overlying semipermeable confining bed. The source of this leakage is assumed to be a reduction in evapotranspiration from the overlying water table aquifer. The hydrologic coefficients in the coupled aquifer model were calibrated from observed pumping and water table data; water table and artesian aquifer drawdowns were estimated for different pumping rates. A coefficient of 0.00112 gpd per cu ft was obtained by matching calculated water table drawdowns to observed water table drawdowns caused by five production wells in the park. Five alternative plans for further well development were explored. The best plan recommended that the central and eastern parts of the park be developed. (Cassar-FRC)

DISSOLUTION OF SALT DEPOSITS BY BRINE DENSITY FLOW,
New Mexico Univ., Albuquerque. Dept. of Geology.
R. Y. Anderson, and D. W. Kirkland.
Geology, Vol 8, No 2, p 66-69, February, 1980. 4 Fig, 12 Ref.

Descriptors: *Salts, *Radioactive waste disposal, *Model studies, Waste disposal, Radioactive wastes, Flow, Flow system, Brines, Water pollution sources.

A brine density flow model is applied to the dissolution of evaporites, which has implications for the use of evaporite deposits for the storage of radioactive waste. A model simulating brine flow was constructed in which a source (aquifer) was connected to an overlying chamber containing salt by a capillary tube 0.54 m long and 0.0015 m in diameter. Water was driven through the tube by brine density difference alone and removed salt from the overlying chamber at a rate of about 1 gm/min. Continuous two way flow developed. Dissolution by means of brine flow within the Delaware Basin in western Texas is discussed, and it is suggested that similar processes may operate in other evaporite basins. Fracture systems that provide communication between pressurized and flowing fresh water aquifers and salt bodies have the potential for developing brine flow and a dissolution system. This can lead, as it has in the Delaware Basin, to collapse breccias. The potential for deep-seated dissolution by means of brine flow should be added to factors considered in risk assessment programs when considering waste depositories in evaporites. (Small-FRC)

2G. Water In Soils

MICROBIAL MOBILIZATION OF CALCIUM AND MAGNESIUM IN WATERLOGGED SOILS,
National Aeronautics and Space Administration, Moffett Field, CA. Ames Research Center.
M. P. Silverman, and E. F. Munoz.
Journal of Environmental Quality, Vol 9, No 1, p 9-12, January-March, 1980. 2 Fig, 3 Tab, 18 Ref.

Descriptors: *Soil water, *Calcium, *Magnesium, *Bacteria, Metabolism, Microbiological studies, Anaerobic conditions, Aerobic conditions, Biodegradation, Soil chemistry.

Direct measurements were made of changes in the concentrations of Ca and Mg in soil solutions as a consequence of microbial glucose metabolism and of the rates of Ca and Mg mobilization as affected by the presence or absence of atmospheric 02. Twelve California soils were amended with 0.5% glucose solution and incubated in air and anaerobically for two weeks under waterlogged conditions. In soil solutions incubated in air, there was a decrease of 1 to 2 units in the pH relative to control soils incubated without glucose. There was also a 2.4- to 29.4-fold increase in the Ca content and a 0.7- to 41-fold increase in the Mg content. Under anaerobic incubation a similar decrease in pH was determined, as well as 2.7- to 15.3-fold increases in Ca and 1.5- to 47-fold increases in Mg. Under incubation in air, the amounts of Ca and Mg increased for 3 to 10 days and then decreased. Under anaerobic conditions, concentrations reached maximum values in 7 to 10 days and did decrease later. Microbial production of various organic metabolites from glucose may be responsible for the release of Ca and Mg from exchange sites. In air, these metabolic products become susceptible to biodegradation, but they are relatively stable under anaerobic incubation. (Small-FRC)

A MATHEMATICAL MODEL FOR PREDICTING MOISTURE FLOW IN AN UNSATURATED SOIL UNDER HYDRAULIC AND TEMPERATURE GRADIENTS,
Saskatchewan Univ., Saskatoon. Dept. of Civil Engineering.
V. Dakshanamurthy, and D. G. Fredlund.
Water Resources Research, Vol 17, No 3, p 714-722, June, 1981. 9 Fig, 2 Tab, 24 Ref.

Descriptors: *Unsaturated flow, *Soil properties, *Pore pressure, Pore water, Soil gases, Soil water, Model studies, Mathematical models, Soil water movement.

A model is developed to predict the moisture flow in an unsaturated soil as a result of hydraulic and temperature gradients. Three partial differential equations (heat flow at above-freezing conditions, water phase and air phase) are solved simultaneously for changes in the combined thermal and hydraulic boundary conditions. Darcy's law is used to describe the flow in the water phase; Fick's law for the air phase; and Fredlund and Morgenstern's constitutive equations for the volume change of an unsaturated soil. Solving the equations produces the temperature, pore water pressure, and pore air pressure distribution with space and time in an unsaturated soil. From these values the quantity of moisture flow may be calculated. Four example problems involve prediction of the moisture flow in an unsaturated subgrade soil such as that below a highway or airfield. The information may also be used to study the dissipation of pore pressures in the compacted core material of an earthfill dam. (Cassar-FRC)

R. K. Ghosh.
Soil Science, Vol 130, No 2, p 60-63, August, 1980. 1 Fig, 2 Tab, 13 Ref.

Descriptors: *Soil water, *Estimating equations, *Soil properties, Mathematical studies, Soil water potential, Soil science.

An empirical technique was developed to estimate soil-moisture characteristics. Soil-moisture characteristics can be determined directly from soil physical properties and a single measurement of water potential in bars at some moisture content on a volume basis. The procedure is particularly useful when a reliable soil moisture characteristic curve is not available. Usually, the physical properties of soils can be obtained from published records of routine work for any geographical location. The method is applicable for those soils for which the water potential minus the moisture content can be expressed as the water potential equals the air-entry water potential in bars times the moisture content over the saturated water content after this fraction is raised to the power of a constant. Considerable agreement was found between estimated values using this procedure and experimentally determined values. (Small-FRC)

SUBSURFACE DRAINAGE AND SEDIMENT TRANSPORT MODEL,
Florida Univ., Gainesville. Dept. of Agricultural Engineering.
A. B. Bottcher, E. J. Monke, and L. F. Huggins.
Transactions of the ASAE, Vol 23, No 4, p 870-876, July/August, 1980. 5 Fig, 15 Ref.

Descriptors: *Sediment transport, *Mathematical models, *Subsurface drainage, Drainage, Sediments, Mathematical equations, Computer models, Simulation, Groundwater movement, Flow characteristics.

Since root zone drainage is the main incentive for subsurface drainage, most research in this area has concentrated on water movement; however, the waters involved can carry substantial amounts of sediments and nutrients. A computer model was developed which uses the GASP IV simulation language to simulate water flow and sediment movement from a subsurface drainage system and to predict these activities as a function of time for both single and multistorm events. The flow portion of the model uses a one-dimensional form of the Richard's equation and a steady state tile flow formula by Toksoz and Kirtham (1961). The output of the flow portion of the model directly controls the particle detachment portion of the model, which is based on a force balance relationship. The sediment flush observed at the beginning of some flow events is adequately described by an exponential decay function. Data collected from a 17 hectare drainage system on a Hoytville silty clay soil were used for calibration and directly proportional to drain flow, while drain flow and rainfall were continuously recorded. Moisture deficit replenishment coefficients, deep seepage, and saturated hydraulic conductivity were calibrated. The model was verified through simulation of the most active flow period of the two years during which data were collected. Comparison of the model results with observed data indicated that the model can reliably predict water yield, sediment yield, and the sediment concentration curve. There was, however, some difficulty in simulating the actual shape of the flow hydrograph. This model should facilitate planning for compliance with section 208 of the Federal Clean Water Act and provide a base for more complex nutrient and pesticide transport models. (Carroll-FRC)

Agricultural Water Management, Vol 4, No, 1-3, p 63-82, 1981. 9 Fig, 43 Ref.

Descriptors: *Estimating equations, *Soil water, *Solute transport, Mathematical studies, Solutes, Salinity, *Root zone, Water quality, Agriculture, *Netherlands.

An approach is presented to the analysis of simultaneous transport of water and solutes within the root zone and in the region between the water table and drains, ditches, or streams. Equations are presented which indicate that within the root zone the travel speed of the water or solute depends primarily on the components of the overall water balance, the average water content, and the distribution of the water uptake. Recent attempts to infer water uptake from salinity data are discussed, as are transport to drains, ditches, or streams induced by an input distributed uniformly over the soil surface. If the ratio of the half-spacing between ditches, drains, or streams and the depth to the impermeable layer is larger than about five, the following are true: The isotherms are horizontal except close to the outlets, and the transit time density distribution is approximately exponential. Estimates are presented for the retardation due to adsorption, for the influence of reactions, and for the influence of dispersion. (Small-FRC)

MODELING WATER FLUX ON STRIP-MINED LAND,
Science and Education Administration, Northeast Watershed Research Center, University Park, PA.
A. S. Rogowski, and B. E. Weinrich.
Transactions of the ASAE, Vol 24, No 4, p 935-940, July/August, 1981. 6 Fig, 4 Tab, 17 Ref.

Descriptors: *Model studies, *Flow measurement, *Soil water, Fluid flow, Flow pattern, Flow profiles, Spoil banks, Mine wastes, Strip mine wastes, Strip mines, Appalachia, *Land reclamation.

An attempt was made to model numerically the infiltration and redistribution of water in reclaimed topsoiled and nontopsoiled Appalachian minesoils. In these minesoils, large size fractions predominate. It was determined that infiltration and redistribution of applied water on topsoiled spoil profiles could be adequately modeled with numerical techniques using either experimentally determined values or moisture characteristics corrected for coarse fragment content and hydraulic conductivities derived from seepage flux. On nontopsoiled profiles, numerical techniques appear inadequate, and a better fit to experimental data can be obtained by subtracting from the flux the amount of water retained by the fine particles and the amount retained on the surface of coarse fragments and then considering the flux to be a function of gravity alone. However, even this approach is not completely satisfactory. At times, when the profile is reasonably dry, water seems to move rapidly through larger channels in the coarse spoil materials without appreciably wetting the rest of the profile. (Baker-FRC)

DRYLAND MANAGEMENT FOR SALINITY CONTROL,
J. Van Schilfgaarde.
Agricultural Water Management, Vol 4, No 1/3, p 383-391, 1981. 18 Ref.

Descriptors: *Salinity, *Water quality management, Water quality, Water resources development, Evapotranspiration, Salt balance, Salts, Farming, *Cropland, Vegetation, Reforestation, Recharge basins, *Great Plains.

Management of salinity in dryland areas may be approached through the maintenance or enhancement in situ of agricultural production, or it may be approached through increasing the yield of good quality water. In the Northern Great Plains of North America, the primary concern is the loss of agricultural production, and solutions to this are sought through the prevention of new and the reclamation of existing salt seeps. This can be accomplished at the recharge site by changing the water balance, or dealt with downstream. In the Red River Valley of North Dakota a different problem exists in that some 160,000 ha of agricultural lands have saline water tables near the surface. In the Lower Rio Grande Valley of Texas, some 40,000 ha of cultivated, nonirrigated soils have salinity problems. The problem facing Western Australia is similar to that of the Northern Great Plains. Excess water percolation due to changes in vegetation resulted in increased lateral movement through semiconfined aquifers. The salts involved are dominantly chlorides deposited in rainfall, and more emphasis is placed here on downstream water quality than on agricultural production. In order to correct dryland salinity problems, various soil properties must be investigated. The most important soil property for the evaluation of water and salt fluxes is the hydraulic conductivity. There are still many difficulties with measuring this property. When changes in water quality are the primary item of interest, the historically well-developed application of potential theory is more useful when interpreted in terms of the stream function rather than the potential function. SOIL PERCOLATION TESTS,
Indian Health Service, Seattle, WA. Office of Environmental Health.
M. E. Peterson.
Journal of Environmental Health, Vol 42, No 4, p 182-186, January/February, 1980. 2 Fig, 7 Ref.

Descriptors: *Soil properties, *Percolation, *Soil water, Leaching, Seepage, Water loss, Infiltration, Capillarity, Measuring instruments, Testing procedures, Standards.

Even though there is severe criticism of the percolation test, it is still used consistently by private, county, state, and federal agencies throughout the United States. Unless the operator is keenly aware of the sources of error in this test, accurate results will be the exception, not the rule. A recommended procedure is offered. Three or more holes should be dug, spaced uniformly over the proposed site, avoiding the use of tools that will compact or smear the soil interface of the holes. Holes should have a diameter of exactly 8 inches. The bottom and sides of the holes should be carefully scraped with a hard rake or other instrument to provide as natural a soil interface as possible, and loose material removed from the bottom of the holes. Perforated liners should be inserted vertically in the holes and gravel or some other porous supporting material carefully placed between the outside of the liner and the hole wall. About 2 in of gravel shold be added to the bottom of the hole. Holes should be presoaked to assure saturation and swelling of the soil. The percolation time is then measured. A percolation tube is described which facilitates the performance of the test. In addition to performing a percolation test at the site, it is highly recommended that a deep boring be made to look for high groundwater elevation and the presence of bedrock or other unique soil boundaries. SAMPLING EMERGING CHIRONOMIDAE (DIPTERA) WITH SUBMERGED FUNNEL TRAPS IN A NEW NORTHERN CANADIAN RESERVOIR, SOUTHERN INDIAN LAKE, MANITOBA,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
D. M. Rosenberg, A. P. Wiens, and B. Bilyj.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 6, p 927-936, June, 1980. 7 Fig, 4 Tab, 14 Ref.

Descriptors: *Midges, *Sampling, *Population density, Lakes, Trap efficiency, Trapping, Canada.

As part of a study on the effects of reservoir formation on Chironomidae in Southern Indian Lake, the experimental design is discussed and the sampling characteristics of the submerged funnel traps are described. Clay, bedrock, and marsh shorelines were sampled at 1.0, 2.0, 3.5, and 4.5 m depths with four replicate traps at each location. The most common offshore species differed from the most common inshore species. All offshore species were similar but inshore marsh species differed from clay and bedrock species. Precision was estimated at + or - 30% for the twelve traps at each depth and 16 traps for each shoreline type. A minimum of four traps was required to interpret emergence patterns of the most common species with one emergence peak while 16 were required if there were two emergence peaks. Continuous and discontinuous trapping gave similar results. Results indicate that the optimum sampling strategy for mesotrophic lakes would be to trap discontinuously and use many traps. (Small-FRC)

DIEL VARIATIONS OF SELECTED PHYSICO-CHEMICAL PARAMETERS IN LAKE KISSIMMEE, FLORIDA,
Florida Dept. of Environmental Regulation, Tallahassee.
C. W. Dye, D. A. Jones, L. T. Ross, and J. L. Gernert.
Hydrobiologia, Vol 71, No 1/2, p 51-60, May 27, 1980. 7 Fig, 3 Tab, 30 Ref.

Descriptors: *Water quality, *Productivity, *Shallow water, Photosynthesis, *Lake Kissimmee, Florida, Lakes, *Physicochemical properties, Mixing, Conductivity, Wind, Destratification, Hydrogen ion concentration, Dissolved oxygen, Temperature.

Lake Kissimmee, Florida (137 sq km, mean depth 2.5 meters) may be typical of the state's lakes in the central portion of the peninsula. The diel depth profiles of dissolved oxygen, pH, temperature and conductivity made at 2 stations from July 1974 to June 1975 suggest that stratification does not occur. However, a large temperature gradient (about 5 degrees C) appeared on 2 occasions, in July and December 1974, on clear, dead calm days. Generally, any temperature differences disappeared with convective cooling at night and with wind mixing. Dissolved oxygen levels were high, maximum 11.6 mg per liter, and on rare occasions, as low as 4 mg per liter at the bottom during extreme calm in summer. Photosynthesis was the primary factor regulating pH, which was maximum in summer and in afternoon, coinciding with periods of maximum productivity. Conductivity was highest in the wet summer months and lowest during the winter dry season. The anomalous summer increase was probably a result of sewage effluent released into lakes in the Upper Basin chain which in turn flowed into Lake Kissimmee. In winter, water is not discharged from the Upper Basin. (Cassar-FRC)

RELATIONSHIP BETWEEN THERMAL STABILITY AND SUMMER OXYGEN DEPLETION IN A PRAIRIE POTHOLE LAKE,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
M. H. Papst, J. A. Mathias, and J. Barica.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 9, p 1433-1438, September, 1980. 6 Fig, 14 Ref.

Descriptors: *Lakes, *Temperature effects, *Oxygen depletion, Eutrophication, Seasonal variation, Algal growth, Prairies, Thermal stratification, Lake breezes, Mixing, *Fishkill.

Periods of oxygen depletion in prairie pothole lakes which cause summer fishkill have been associated with the collapse of algal blooms, but are not necessarily caused by this collapse. The thermal instability which sometimes follows this collapse plays an important role in summerkill. Thermal stability of the pothole lakes is dependent on wind stress and night-time air temperatures. The present results aid in determining the speed with which oxygen depletion may occur, and correlate the occurence of periods of lake oxygen depletion with variations in weather conditions. The algal biomass may collapse without severe oxygen depletion in these lakes. (Geiger-FRC)

MODEL OF THE SEASONAL DYNAMICS OF AN ECOSYSTEM OF A SHALLOW LAKE,
Akademiya Nauk SSSR, Moscow. Inst. of Limnology.
O. V. Belyakova.
Water Resources (English Translation), Vol 7, No 5, p 450-457, September/October, 1980. 4 Fig, 24 Ref. Translated from Vodnye Resursy, No 5, p 130-139, September/October, 1980.

Descriptors: *Mathematical models, *Seasonal variation, *Ecosystems, *Lakes, Mathematical equations, Water temperature, Temperature effects, Solar radiation, Biomass, Aquatic productivity, Energy, Shallow lakes.

In order to understand and predict the reaction of a lake ecosystem to varying external effects, it is first necessary to create a mathematical model of the seasonal dynamics of the components of the ecosystem. The development of a mathematical model of the seasonal dynamics of the biomass and production of the main trophic groups of aquatic organisms and of the concentrations of biogenic elements is discussed. The inputs of the system are the mean monthly values of absorbed solar radiation, the temperature of the water mass, inflow and outflow of the lake, and the amount of production of macrophytes. The outputs of the system include dissipation of heat energy during the vital activity of aquatic organisms, the biomass of chironomids that have emerged and flown away, and the consumption of zooplankton and benthos by fishes. The results obtained on the model were compared with data obtained by direct observation on a mesotrophic lake in northwestern U.S.S.R. This comparison showed that the model provided a satisfactory reproduction of both the overall level of development and seasonal dynamics of the main components of the lake ecosystems. This model can be used to evaluate the role of the main trophic links in the seasonal dynamics of the flow of material and energy in the lake and to evaluate the possible responses of the system to quantitatively different regimes of the input variables. However, it is not suitable for evaluation of potential responses to large disturbances which would create the basis for a different energy regime. (Carroll-FRC)

PROBABILITY-THEORETICAL ANALYSIS OF FLUCTUATIONS IN THE LEVEL OF A CLOSED WATER BODY,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
S. V. Muzylev.
Water Resources (English Translation), Vol 7, No 5, p 403-417, September/October, 1980. 6 Fig, 31 Ref. Translated from Vodnye Resursy, No 5, p 21-41, September/October, 1980.

Descriptors: *Closed lakes, *Hydrologic budget, *Mathematical studies, Mathematical equations, Climatology, Water level fluctuations, Lakes, Stochastic process.

Closed lakes are water bodies from which rivers do not flow. The natural regimes of most of these closed water bodies have been substantially disturbed by economic measures related primarily to irrigation and streamflow regulation. In order to predict the regime of closed lakes, it is first necessary to develop a physical model which correctly reflects the regularities of the fluctuations of their levels. Previous models based on the stochastic character of river inflow and apparent evaporation used a discrete form of notation of the annual increments of components of the water balance. However, all physically real stochastic processes represent continuous functions of time. The use of the concept of continuous processes reduces the problem of water level fluctuations in a closed lake to classical problems of nonequilibrium statistical mechanics and statistical radio engineering. A continuous model describing the fluctuations of the level in a closed water body was used to obtain a quantitative estimate of the effect of the product of level fluctuations and river inflow on the statistical characteristics of the level. This effect can be neglected when the inflow variability is small, but not when the coefficients of variation of the inflow are close to unity. In the simplest case, the correlation function of level fluctuations corresponds to the component of the two-dimensional Markov process. When lags far exceed the correlation time of inflow and apparent evaporation, a first-order Markov process describes the level fluctuations sufficiently well. This continuous model permits identification of the characteristics to the case of cross correlation of the river inflow and apparent evaporation. (Carroll-FRC)

MICROBIAL METABOLISM OF N-NITROSODIETHANOLAMINE IN LAKE WATER AND SEWAGE,
Cornell Univ., Ithaca, NY. Soil Microbiology Lab.
J. R. Yordy, and M. Alexander.
Applied and Environmental Microbiology, Vol 39, No 3, p 559-565, March, 1980. 7 Fig, 16 Ref.

Descriptors: *Nitrogen compounds, *Metabolism, *Lakes, *Wastewater, Microbial degradation, Microorganisms, Seasonal variations, Nitrosamines, Mineralization.

The transformation of N-nitrosodiethanolamine (NDEIA) was studied in samples of lake water and sewage. Water samples were taken from North Lake in the Adirondack Preserve and from Cayuga Lake, both in New York State. Samples were taken about 1 m from the shore, at surface level. Sewage samples at pH 7.8 were collected from the primary settling tank at the Ithaca, NY sewage treatment plant. The mineralization of NDEIA in samples of these three waters was studied. At NDEIA concentrations of 1.1 microgram/ml, mineralization was never noted in the Cayuga Lake and North Lake water samples, even though the process was examined with water collected at different times of the year. In sewage, NDEIA was mineralized, with over 40% of the carbon added as NDEIA being recovered as CO2 when the experiments was completed. Even though NDEIA was not mineralized in the lake water samples, the nitrosamine was metabolized. Breakdown of about 1.0 micrograms of NDEIA per ml in North Lake water and Cayuga Lake water was caused by microorganisms. In North Lake only partial degradation was noted in the September sample, which suggests that depletion of an essential nutrient occurred in the water sample. In sewage, no seasonal variation on the microbial conversion was noted, and the products of metabolism were slowly mineralized. NDEIA was apparently converted to the same organic products in all three samples. Data suggest that these products were modified dimers of NDEIA. (Baker-FRC)

INFLUENCE OF SEASONAL TEMPERATURE ON THE TEMPERATURE OPTIMA OF BACTERIA IN SEDIMENTS OF LAKE GEORGE, NEW YORK,
Oregon State Univ., Corvallis. Dept. of Microbiology.
D. L. Tison, D. H. Pope, and C. W. Boylen.
Applied and Environmental Microbiology, Vol 39, No 3, p 675-677, March, 1980. 1 Fig, 1 Tab, 12 Ref.

Descriptors: *Bacteria, *Temperature effects, Lakes, *Lake George, Seasonal variations, Sediments, Nutrients, Nutrient cycling, Littoral zone, Lake sediments, New York.

The possibility of temperature limiting microbial activity in Lake George during periods of nutrient input and throughout the winter was investigated. Sediment samples were collected from a depth of 1 meter with an Ekman dredge and diluted 1:1 (vol/vol) with lake water. Temperature optima for the heterotrophic utilization of glucose and an amino acid mixture were determined throughout the year. The temperature optimum decreased with decreasing in situ temperature in the fall and winter, suggesting that selection for or adaptation by a psychrotrophic bacterial population occurred. Replicate plating of bacterial isolates from 3 and 20 degrees C indicated that a psychrotrophic bacterial population was present in the sediments throughout the year. These results indicate that decomposition and nutrient cycling processes in the sediments within the littoral zone of Lake George were probably not completely inhibited by winter temperatures, although the process rates were decreased. Utilization rates for glucose in January were about 30% of those in August, but this was thought to be due to a decrease in the numbers of active microorganisms or limitations due to factors other than temperature during the winter. Descriptors: *Lake sediments, *Phosphates, *Algal growth, Eutrophication, Suspended sediments, Bottom sediments, Phosphorus, *Nutrients, Nuisance algae, Algae, Catchment areas, Reservoirs, Mathematical studies, *South Africa.

The amount of sediment phosphate available as nutrients for algal growth was examined in sediments from 38 South African impoundments. Selenastrum capricornutum was used in a bioassay technique to determine the availability of sediment phosphate in a 21 day incubation period. When impoundments were grouped according to the geological formation of their catchments, the algal available phosphate fraction and the inorganic phosphate content of the sediments were correlated. Two regression equations were proposed to calculate the algal available phosphate level of the sediments when the inorganic phosphate levels of the sediments are known. In turbid or shallow impoundments the phosphate content of suspended sediments should also be considered as a source of algal nutrients. It was suggested that these data be considered when imposing phosphate standards in South Africa for eutrophication management. (Geiger-FRC)

DISTRIBUTION AND BIOLOGICAL AVAILABILITY OF REACTIVE HIGH MOLECULAR WEIGHT PHOSPHORUS IN NATURAL WATERS IN NEW ZEALAND,
Department of Scientific and Industrial Research, Taupo (New Zealand). Freshwater Section.
E. White, and G. Pane.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 4, p 664-669, April, 1980. 2 Fig, 4 Tab, 8 Ref.

Descriptors: *Phosphorus, *Eutrophic lakes, *Algal growth, Streams, Phosphates, Eutrophication, Dissolved solids, Water pollution effects, Turnover time, Absorption, Nutrients, Chlorophyta, Algae, *New Zealand.

Dissolved phosphorus which is not orthophosphate is present in many eutrophic lakes and streams of the central volcanic plateau of North Island, New Zealand. One of the reactive phosphorus components was shwon by Sephadex gel chromatograms to have a molecular weight of over 5000, while a second component elutes as phosphate-phosphorus. The reactive high molecular weight phosphorus (RHMW-P) usually forms only a small fraction of the dissolved reactive phosphorus (DRP) in streams. In some eutrophic lakes, a characteristic distribution of the two forms exists and the RHMW-P/DRP ratio may be as high as 70-80%. In summer months phosphate-phosphorus dominates over RHMW-P, a situation consistent with the long phosphate turnover rates peculiar to many lakes of this region. Algal growth responses to phosphorus uptake were similar for phosphate-phosphorus and RHMW-P, but the amount of RHMW-P taken up by Chlorella varied from lake to lake. This caused problems in relating lake DRP levels to algal growth responses. (Geiger-FRC)

COMPARISON OF A FEW SYSTEMS FOR THE DETERMINATION OF SAPROBIC AND TROPHIC DEGREE ON THE BASIS OF PLANKTON DATA,
Katholieke Univ., Nijmegen (Netherlands) Lab. of Aquatic Ecology.
G. J. Van Nuland, and J. F. G. M. Meis.
Hydrobiologia, Vol 70, No 3, p 251-256, May 2, 1980. 1 Fig, 2 Tab, 27 Ref.

Descriptors: *Plankton, *Saprobic index, *Trophic level, Ecosystems, Mesotrophy, Water quality, Lakes, Biological properties, Phytoplankton, Zooplankton, Nutrients, Species composition, Comparison studies, Aquatic envrionment.

The biological quality of an aquatic environment, the Haarsteegse Wiel, Vlijmen, the Netherlands, was determined by five different methods. Two methods involved the saprobity; two, the trophic level; and one, chemical data. This water body, which formed following dike bursts on the River Meuse in 1610 and 1740, was studied from April to October 1977. The two methods for determining saprobic index showed, in good agreement, that the water was within the transition range between beta-mesosaprobic and oligosaprobic. The Zelinka and Marvan (1961) method, developed in Czechoslovakia, is to be used with a well-defined community, such as plankton, benthos, or epiphyton (in this study, plankton) and requires an extremely accurate identification of organisms. The Dresscher and van der Mark (1976) technique uses several indicator species in a formula for saprobic index. Since detailed identification is not necessary, it saves time. Objections to this method are the generalization and the disregard of quantities of species found. The methods for determining trophic degree, those of Hutchinson (1967), Rawson (1956), and chemical data, all indicated the Haarsteegse Wiel to be mesotrophic. (Cassar-FRC)

VERTICAL DISTRIBUTION OF MONOSACCHARIDES IN LAKE WATER,
Tokyo Metropolitan Univ. (Japan). Dept. of Chemistry.
M. Ochiai, and T. Hanya.
Hydrobiologia, Vol 70, No 1/2, p 165-169, April, 1980. 3 Fig, 3 Tab, 12 Ref.

Descriptors: *Carbohydrates, *Organic matter, *Monosaccharides, *Lakes, Glucose, Galactose, Eutrophic lakes, Dystrophic lakes, Water analysis, Phytoplankton, Heterotrophic bacteria.

Eight common monosaccharides of the dissolved organic matter were measured in 3 Japanese lakes: Nakanuma, small and eutrophic; Suwako, shallow and eutrophic; and Shirakoma-ike, dystrophic. The ratio of concentrations of carbohydrates analyzed by gas chromatography to those analyzed by the anthrone method ranged from 30.5 to 121% in Suwako, 12.9 to 51.4% in Nakanuma, and 21.2 to 38.6% in Shirakoma-ike. In surface water of Lake Suwako (eutrophic) glucose and galactose represented 40% and 24.4%, respectively, of the carbohydrates, and 16.4 to 19.2% and 18.5 to 19.8%, respectively, in the deeper water. Rhamnose made up 12.2% of surface water carbohydrates and 23.9 to 25.8% in deeper waters. Ribose and arabinose were low from surface to 5 meters; fucose, xylose, and mannose were present in intermediate concentrations. Lake Nakanuma monosaccharide levels were on the same order. In dystrophic Lake Shirakoma-ike, the vertical profiles of most monosaccharides were relatively uniform; galactose, glucose, and mannose were in greatest concentrations, but at smaller concentrations than in the eutrophic lakes. (Cassar-FRC)

CLASSIFICATION OF CENTRAL AMAZON LAKES ON THE BASIS OF THEIR MICROBIOLOGICAL AND PHYSICO-CHEMICAL CHARACTERISTICS,
Max Planck Inst. fuer Limnologie zu Ploen (Germany, F.R.). Dept. of Tropical Ecology.
H. Rai, and G. Hill.
Hydrobiologia, Vol 72, No 1/2, p 85-99, July 10, 1980. 10 Fig, 4 Tab, 51 Ref.

Descriptors: *Classification, *Physicochemical properties, *Microbiological studies, Algae, Nutrients, Amazon River, Flood plains, Lakes, Oxbow lakes, Varzea lakes, Ria lakes, Phytoplankton, Primary productivity, Productivity, Saprophytic bacteria, Bacteria, Chlorophyll a, Deltas, Heterotrophic bacteria, Water quality, *Lake classification, *Amazon lakes, South America.

The physical, chemical, and microbiological characteristics of 24 Central Amazonia Varzea and Ria Lakes, lateral to the Rio Negro and Rio Solimoes, were studied during the low water phase of 1975. Three water types (white, mixed, and black) were differentiated on the basis of physical and nonmetallic inorganic constituents. The eight white water lakes were highest in dissolved oxygen, 5.2-8.9 mg per liter; nitrates, 3.4-52.2 micrograms per liter; ammonium, 78-653 micrograms per liter; Fe(3+), 0.575-16.8 mg per liter; total organic carbon, 8-22.75 mg per liter; pH, 6.6-8.4; and conductivity, 31-80 micro S per cm at 20 degrees C. The 12 black water lakes had the highest Secchi disk transparencies, 95-299 cm. The four mixed lakes were highest in phosphates, 0-49.4 micrograms per liter. Physicochemical parameters with less defined differences among the lakes were: KMnO4, chloride, dissolved organic carbon, and temperature. White water lakes had the highest concentrations of saprobic bacteria, total bacteria, chlorophyll a, and microcrustaceans. Primary production (in mg C per sq meters per day) had a large range: white, 350-1500; mixed, 820-3500; and black 347-10451. Algae in the lakes further characterized the lake waters. White waters were dominated by Melosira, black waters (lower species diversity) by Peridinium, and mixed waters (greatest species diversity) by clean water indicators. (Cassar-FRC)

LIGHT PENETRATION AND THE INTERRELATIONSHIPS BETWEEN OPTICAL PARAMETERS IN A TURBID SUBTROPICAL IMPOUNDMENT,
Orange Free State Univ., Bloemfontein (South Africa). Inst. for Environmental Sciences.
R. D. Walmsley, M. Butty, H. van der Piepen, and D. Grobler.
Hydrobiologia, Vol 70, No 1/2, p 145-157, April, 1980. 7 Fig, 4 Tab, 23 Ref.

Descriptors: *Light penetration, *Turbidity, *Suspended sediments, Transparency, Seasonal variation, Secchi disks, Rust der Winter Dam, *South Africa, Water quality, Subtropical zone, Lakes, *Reservoirs, Stratification, Thermal stratification, Euphotic zone, Silt, Chlorophyll a.

The main factors regulating the temporal and spatial variations in water transparency in a turbid subtropical impoundment (Rust der Winter Dam, South Africa) were allochthonous inputs of silt during summer floods, impoundment morphometry, and the warm monomicitic thermal cycle. Statistically significant relationships were established between Secchi disk transparency (0.6-3.00 meters), surface water turbidity (4.2-25 JTU), mean diffuse attenuation coefficient (0.64-2.00 per meter), and beam attenuation coefficient (1.14-10.60 per meter without a filter). These relationships allowed an approximation of the 1% of surface light intensity depth (corresponding with the euphotic zone) to be made if any one of the parameters were known. Blue light attenuation was greater than red light attenuation because of the effects of suspended clay particles. (Cassar-FRC)

CHEMICAL COMPOSITION OF INTERSTITIAL WATERS IN BOTTOM SEDIMENTS OF SOME POLISH LAKES OF THE WIGRY GROUP (NORTHERN POLAND),
Akademia Rolnicza, Warsaw (Poland). Zaklad Limnologii i Rybactwa.
A. Woroniecka-Stasiak.
Acta Hydrobiologica, Vol 22, No 4, p 347-360, 1980. 5 Fig, 2 Tab, 12 Ref.

Descriptors: *Interstitial water, *Lakes, *Chemical properties, Bottom sediments, Acidity, Alkalinity, Hydrogen ion concentration, Carbon dioxide, Organic acids, Ammonium salts, *Poland, Chemical composition.

The chemical composition of interstitial waters in the sediments of Wigry lakes was investigated in nine lakes. Fifty-one to 65% of sediment weight was interstitial water, and the most important feature of the water was the acid pH, which ranged from 5.6 in Lake Suchar to 6.9 in Lakes Krzywe and Omulowek. High alkalinity was found in the interstitial waters of Lakes Wigry, Omulowek, Krzywe, Muliczne, and Przetaczek. The remaining

lakes had water of the acido-dystropic type. A linear relationship was found between alkalinity and the pH values of interstitial waters saturating some sediments. In harmonic lakes, the acid relation was conditioned by the occurrence of free CO2, and in disharmonic lakes by the occurrence of free CO2 and organic acids. Interstitial waters were a source of organic compounds and mineral salts to the hypolimnion and contained large amounts of iron and phosphorus. Large amounts of ammonium salts were found. In harmonic lakes, denitrification was responsible for the absence of nitrates and nitrites. (Small-FRC)

INTERACTION OF ORTHOPHOSPHATE WITH IRON (III) AND ALUMINUM HYDROXIDES,
Technische Hogeschool Twente, Enschede (Netherlands). Dept. of Chemical Engineering.
L. Lijklema.
Environmental Science and Technology, Vol 14, No 5, p 537-541, May, 1980. 5 Fig, 34 Ref.

Descriptors: *Coagulation, *Phosphates *Lakes, *Iron, *Aluminum, Water treatment, Tertiary wastewater treatment, Wastewater treatment, Chemical reactions, Hydrogen ion concentration, Eutrophication, Lake sediments, Metals, Adsorption.

The influence of pH and aging on phosphate binding by Fe(3+) or aluminum hydroxides is pertinent to water and wastewater treatment and to phosphate exchange between sediments and overlying water in lakes. In laboratory studies, similarly-shaped adsorption isotherms of phosphates on Fe(3+) hydroxide or aluminum hydroxide were obtained at pH values of 5, 6, 7, and 8. Phosphate-P concentrations varied from 0 to 0.2 nmol per liter; ratios of P adsorbed per Fe concentration varied from 0.05 to 0.2. Phosphate adsorption was greater at lower pH and at higher phosphate concentrations. More phosphate was adsorbed when the hydroxides were formed in situ. Freshly precipitated Fe(3+) hydroxide adsorbed more phosphate than 1-day-old precipitates. Ratios of adsorbed phosphate to Fe increased linearly with time over the 1000 hours of the study. Adding acid or base to shift the pH 2 units showed that adsorption and desorption changes are not completely reversible. Practical conclusions drawn from this work are: (1) rapid initial mixing of coagulants in treatment plants is most effective; (2) at low temperatures and slightly acid waters the effective phosphate adsorption can result in negatively charged phosphated complexes, resisting coagulation; (3) at pH 5 phosphate can remove Fe from iron-containing water by membrane filtration with a 0.2 micrometer filter; (4) in lakes, a variation of pH produced by photosynthetic activity can influence the adsorption capacity of the sediment; (5) high release of phosphate and Fe can occur in shallow lakes under reducing conditions throughout the sediment and with high pH in the overlying water. THE EFFECT OF SEASON AND LOCATION ON PHOSPHOADENYLATE CONCENTRATIONS AND ADENYLATE ENERGY CHARGE IN TWO SPECIES OF FRESHWATER CLAMS,
Savannah River Ecology Lab., Aiken, SC.
J. P. Giesy, and G. W. Dickson.
Oecologia, Vol 49, No 1, p 1-7, 1981. 3 Fig, 8 Tab, 36 Ref.

Descriptors: *Clams, Ponds, Reservoirs, Lakes, *Savannah River impoundments, Mollusks, Rivers, Phosphates, *Adenosine triphosphate, Baseline studies, Seasonal variation, Monitoring, *Bioindicators, Cooling ponds, *Nuclear powerplants.

Seasonal and size related variations of adenosine triphosphate (ATP), adenosine diphosphate (ADP), 5'-adenylic acid (AMP) and total adenylate concentrations were determined in the papershell clam and Asian clam. The adenylate energy charge was also investigated. Papershell clams were collected from the thermally enriched portion of Par Pond, an impoundment on the U.S. Department of Energy's Savannah River Plant, near Aiken, SC. Asian clams were collected from the Savannah River adjacent to the Savannah River Plant. Seasonal variations were readily observable in all three adenylates as well as in the total adenylate concentration and the adenylate energy charge for each species. The periods of active reproduction cycles for each species were closely tied with the fluctuations in adenylates and energy charges. Possible relationships of the various concentrations measured to the shell length of individual animals were investigated. The different points of collection did not appear to influence the value of the adenylate energy charge on individuals of either species. The adenylate energy charge of the Asian clam was seen to increase after acclimation had occurred to laboratory surroundings and feedings had begun. A deeper understanding of adenylate energy charges and adenylate concentrations is necessary before these parameters can be used as part of a natural background in monitoring programs. (Baker-FRC)

FACTORS INFLUENCING FISH DISTRIBUTION IN TWO DESERT RESERVOIRS, CENTRAL ARIZONA,
Arizona State Univ., Tempe. Forestry Sciences Lab.
J. N. Rinne, W. L. Minckley, and P. O. Bersell.
Hydrobiologia, Vol 80, No 1, p 31-42, April, 1981. 4 Fig, 10 Tab, 47 Ref.

Descriptors: *Reservoirs, *Fish, *Limnology, Temperature effects, Thermoclines, Dissolved oxygen, Seasonal variation, Littoral environment, Littoral zone, Euphotic zone, *Fish populations, *Arizona.

Sampling of fishes, net plankton, phytoplankton pigments, and benthos began in the summer of 1970 and ended in autumn of 1971 in two desert reservoirs in central Arizona. The two reservoirs were Roosevelt Lake and Apache Lake. At full pool Roosevelt Lake approaches Apache Lake in maximum and mean depths, but is far larger, having almost six times the volume of Apache, twice the shoreline, and six times the mean breadth and surface area. The slope is far less severe in Roosevelt Lake. Temperature profiles vary substantially over time in these two low desert lakes, and annual cycles were similar in the two reservoirs. A basic difference between the two was in the depth of the metalimnion, which was located from 10 to 15 m in Roosevelt Lake, and at about half that depth, 5 to 7 meters, in Apache. This was attributable to wind action on the broad, unprotected surface of the former in contrast to the fjord-like nature of Apache Lake. Dissolved oxygen curves generally paralleled seasonal temperature profiles, with high concentrations from surface to bottom during winter and spring and hypolimnic oxygen deficiencies during the summer. Apache Lake was far more transparent. No single factor appeared paramount in delimiting fish population dispersion in the two desert reservoirs. The greatest abundance of fish based on vertical gillnet catches was in the upper 10 meters of water, reflecting the influence of thermocline depth, levels of dissolved oxygen concentration, and euphotic zone. Fish introduced into western reservoirs are intrinsically shallow-water, littoral inhabitants, and remain so due to inherent limnological factors characteristic of mid-latitude lentic systems. GRAZING RATE DETERMINATION OF CORYNONEURA SCUTELLATA WINNERTZ (CHIRONOMIDAE:DIPTERA),
Rhode Island Univ., Kingston. Dept. of Zoology.
D. H. Kesler.
Hydrobiologia, Vol 80, No 1, p 63-66, April, 1981. 1 Fig, 10 Ref.

Descriptors: *Midges, *Littoral zone, Littoral drift, Lakes, *Phytoplankton, Aquatic drift, *Rhode Island, Grazing, Standing crops, Aquatic flora, Aquatic animals, Diptera.

The grazing rate of the larval chironomid Corynoneura scutellata Winnertz (Diptera) was investigated. Sampling was carried out in Nonquit Pond, Rhode Island. C. scutellata larvae were collected from the littoral zone. Grazing rates were determined radiometrically at different temperatures. The resulting temperature-grazing function is given. This function was then applied to field data from Nonquit Pond. A maximum grazing rate of 107 mg dry weight/square meter/day was calculated to have occurred in late June of 1978. Calculated C. scutellata grazing rates were compared to periphyton net accumulation rates. The means of these ratios ranged from 3 to 15% with a maximum of 70%, indicating that these larvae are potentially able to affect periphyton standing crop. (Baker-FRC)

NITROGEN AND PHOSPHORUS RECYCLING IN LAKE SAMMAMISH, A TEMPERATE MESOTROPHIC LAKE,
Washington Univ., Seattle. Dept. of Civil Engineering.
R. B. Birch, and D. E. Spyridakis.
Hydrobiologia, Vol 80, No 2, p 129-138, May, 1981. 3 Fig, 3 Tab, 21 Ref.

Descriptors: *Lakes, *Nutrients, *Nitrogen, *Phosphorus, Mesotrophic lakes, Mesotrophy, Trophic load, Dynamics, *Cycling nutrients.

Nitrogen and phosphorus budgets are presented for spring and summer for the trophogenic and tropholytic zones of Lake Sammamish. The budgets are constructed to evaluate the efficiency of nutrient recycling and increase knowledge of the overall nutrient dynamics. The budgets reveal that uptake and solubilization are the dominant fluxes and that nutrient recycling is generally efficient with the possible exception of early spring during the diatom bloom. Solubilization of particulates is much less in the tropholytic zone than the trophogenic zone. This is due to slower decomposition rates there and to the efficiency of solubilization in the overlying trophogenic zone which results in a relatively small particulate influx. Turnover times for the N and P pools are thus much faster in the trophogenic zone than in the tropholytic zone. In the trophogenic zone, however, the dissolved N pool turns over much more slowly than the dissolved P pool due to its larger size relative to algal

growth requirements. Overall there is a net loss of N and P from the water column in spring, primarily due to sedimentation and denitrification, while in summer there is a small net gain due to sediment release and a slight excess of inflow over outflow. (Baker-FRC)

POTENTIAL IMPACT OF SIZE-SELECTIVE PLANKTIVORY ON PHOSPHORUS RELEASE BY ZOOPLANKTON,
Wisconsin Univ.-Madison.
S. M. Bartell.
Hydrobiologia, Vol 80, No 2, p 139-145, May, 1981. 5 Tab, 28 Ref.

Descriptors: *Zooplankton, *Phosphorus, Lakes, Nutrients, Cycling nutrients, *Predation, Fish.

The speculation that size-selective predation by planktivorous fishes affects rates of phosphorus release by zooplankton at the system level through changes in both mean individual size and biomass of zooplankton was investigated. Comparisons were made of estimated rates of P release from zooplankton in lakes before and after introduction of size-selective predators, and comparisons were made among several lakes with varying abundance of predators. A laboratory model of phosphorus release by Daphnia rosea was implemented for published zooplankton data from the lakes. Size-selective feeding reduced average prey size and increased P release per unit biomass. At the system level, decreased prey standing crop associated with higher planktivore abundance could balance the size dependent increase in P release rate. However, estimates of both net reduction and net increase in rate of P release from zooplankton resulted from model application. Size-selective feeding may be important not only in energetic or evolutionary relationships between predator and prey but also in determination of the relative importance of different pathways of phosphorus flow through pelagic systems. ON LAKE BOTTOM DYNAMICS--THE ENERGY-TOPOGRAPHY FACTOR,
National Swedish Environment Protection Board, Uppsala. Water Quality Lab.
L. Hakanson.
Canadian Journal of Earth Sciences, Vol 18, No 5, p 899-909, May, 1981. 4 Fig, 10 Tab, 13 Ref.

Descriptors: *Lakes, *Bottom sediments, Erosion, Mathematical models, Models, Mathematical studies, Lake morphometry, *Limnology, Lake sediments, Sediments, Lake shores, Lake basins, Dynamics, Basins.

Some of the causal relationships that determine bottom dynamics in lakes are discussed, and a formula is suggested that expresses these causal relationships in terms of simple morphometric parameters. The benefit of such a model is that much valuable information can be gained from a minimum of work. Detailed empirical data from areas dominated by erosion, transportation, and accumulation have been determined for nine Swedish lakes or basins. The model has been calibrated against this set of data. The areal distribution of lake bottom areas dominated by erosion and transportation is governed by an energy factor, a slope factor, and a form factor. The equation which interrelates these factors is presented. Despite the fact that the formula is based on only three morphometrical standard parameters, it yields a surprisingly high correlation, which indicates that it describes the functional relationships in a proper manner. Tests have indicated that this formula is not significantly improved by accounting for the shore irregularity and lake shape factors. It is probable that the model yields the most accurate results for lakes in the size range of 1 to 5000 square kilometers. It is only applicable to single basins. In multi-basin lakes each basin must be treated separately. (Baker-FRC)

SEDIMENT-BASED NUTRITION OF SUBMERSED MACROPHYTES,
Army Waterways Experiment Station, Vicksburg, MS.
J. W. Barko, and R. M. Smart.
Aquatic Botany, Vol. 10, No 4, p 339-352, May 1981. 7 Tab, 48 Ref.

Descriptors: *Macrophytes, *Nutrients, *Sediments, Nitrogen, Phosphorus, Potassium, Uptake, Lakes, Plant growth, Vegetation, *Rooted aquatic plants.

An evaluation was made of the abilities of four submersed freshwater macrophytes to mobilize nitrogen, phosphorus, and potassium from different sediments in relation to their respective requirements for these nutrients. The four species involved were Bacopa caroliniana (Walt.) Robbins, Myriophyllum brasiliense Camb., Potamogeton illinoensis Morong, and Proserpinaca palustris L. With all species, N and P were readily mobilized from each of the sediments and concentrated in plant shoots at levels well above those required for growth. However, the mobilization of K from all sediments was far less effective and may have limited the growth of the species considered. Sediments represent a large and important source of N and P for rooted aquatic macrophytes, but K is probably supplied to these plants primarily from the water. N and P were excreted in only small amounts, if at all, from the species during active growth. However, considerable quantities of these nutrients can be released to the water due to plant senescence and associated decay. This represents an important mode of sediment-nutrient recycling in aquatic systems. (Baker-FRC)

AMMONIA AND NITRATE UPTAKE IN THE LOWER GREAT LAKES,
National Water Research Inst., Burlington (Ontario). Aquatic Ecology Div.
T. P. Murphy.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 9, p 1365-1372, September, 1980. 7 Fig, 1 Tab, 26 Ref.

Descriptors: *Lakes, *Primary productivity, *Nitrogen, *Limiting nutrients, Spectrophotometry, *Ammonia, *Great Lakes, Water analysis, Nutrients, Nitrate, Cycling nutrients, Data collections, Incubation, Lake Erie, Lake Ontario.

A simple radiolabeled N technique of emission spectrophotometry has been used to obtain a large data base for nitrate and ammonia uptake kinetics in Great Lakes Erie and Ontario. Short-term incubatin of water samples was necessary to prevent induction of nitrate uptake or changes in the rate of ammonium ion uptake which took place in long-term incubations. During most of the summer, uptake rates of nitrate and nitrate regeneration rates were generally slow. The slow turnover rate of particulate N, low levels of nutrients, and high affinities for ammonia suggest that the summertime primary productivity of the Lower Great Lakes is limited by nitrogen concentrations. LIMNOLOGICAL CHARACTERISTICS OF SEVERAL LAKES ON THE LAKE WALES RIDGE, SOUTH-CENTRAL FLORIDA,
Bucknell Univ., Lewisburg, PA. Dept. of Biology.
W. F. McDiffett.
Hydrobiologia, Vol 71, No 1/2, p 137-145, May, 1980. 7 Fig, 3 Tab, 21 Ref.

Descriptors: *Nutrients, *Primary productivity, *Water quality, *Productivity, *Lakes, Eutrophication, *Florida, Phytoplankton, Nitrogen compounds, Phosphorus compounds, Limnology, Watershed development, Chlorophyll a.

Three lakes in southcentral Florida were studied from September 1976 to July 1977 to obtain basic limnological information, focusing on the productivity and nutrient relationships as affected by human activity. The lakes--Annie, Placid, and Francis--are connected seasonally by either natural drainage or man-made canals. Lake Annie is underdeveloped; the other two are partly to completely developed. All three lakes have clear, soft, nutrient-poor water. Primary production and chlorophyll a production is highest in Lake Francis. Productivity estimates (in g carbon per sq meter per year) were 205 for Francis, 75.8 for Annie, and 42.8 for Placid. Water from all three lakes responded to enrichment with N and P, but none to N alone. Lake Francis responded to P addition alone. Francis was judged nearly eutrophic, and the other two lakes oligotrophic in terms of primary productivity, light transmission, and dominant phytoplankton, and mesotrophic in terms of chlorophyll a. The water quality of these lakes appeared to be correlated with development along the shoreline and use of the surrounding watershed. (Cassar-FRC)

FACTORS CONTROLLING PHYTOPLANKTON PRIMARY PRODUCTIVITY IN BYRAM LAKE, MT. KISCO, N.Y., SUMMER, 1977,
Fordham Univ., Bronx, New York. Louis Calder Conservation and Ecology Study Center.
G. S. Kleppel, R. Ingram, and W. B. Samuels.
Hydrobiologia, Vol 70, No 1/2, p 95-101, April, 1980. 3 Fig, 2 Tab, 23 Ref.

Descriptors: *Primary productivity, *Eutrophic lakes, *Water depth, Stratification, Algae, Phytoplankton, Productivity, Eutrophication, Lakes, *Byram Lake, New York.

Accelerated eutrophication and algal blooms in Byram Lake, New York, prompted an investigation of phytoplankton productivity. Results suggest that horizontal and vertical microenvironments exist throughout the lake. At deeper stations, thermal stratification placed inorganic nitrogen in juxtaposition with phytoplankton in the upper metalimnion. At one station, surface productivity was ammonia-limited and bottom productivity was related to P levels. Phytoplankton productivity at a shallow station was inversely related to incident light and temperature. The vascular macrophyte bloom shaded the phytoplankton and decreased its productivity. In late summer the macrophytes decayed and released nutrients. As a result phytoplankton productivity reached a maximum in September. The failure to detect relationships between depth integrated productivity and environmental parameters suggests that the controlling factors were not measured in this study, that multiple parameter interactions regulated productivity, or that different factors were significant at different depths. CHEMICAL COMPOSITION OF LABILE FRACTIONS IN DOM,
Tokyo Metropolitan Univ. (Japan). Dept. of Chemistry.
M. Ochiai, T. Nakajima, and T. Hanya.
Hydrobiologia, Vol 71, No 1/2, p 95-97, May, 1980. 2 Fig, 2 Tab, 8 Ref.

Descriptors: *Organic matter, *Amino acids, *Carbohydrates, Degradation, Microbial degradation, Labile fraction, Dissolved solids, Organic carbon, *Chemical composition, Natural waters, Lakes, Decomposition, Lake Nakanuma, *Japan, *Dissolved organic matter.

The labile fraction (biologically derived compounds such as carbohydrates, proteins, amino acids, and lipids) of dissolved organic matter (DOM) in a eutrophic lake was decomposed under anaerobic and aerobic conditions for 20 days. In

anaerobic decomposition total dissolved organic carbon decreased by 20% (initial concentration 4.19 mg C per liter), dissolved amino acids by 15% (initial concentration 0.49 mg C per liter), and dissolved carbohydrates by 48% (initial concentration 0.43 mg C per liter). In aerobic experiments with the same starting concentration, total dissolved organic C decreased by 26%, dissolved amino acids by 23%, and dissolved carbohydrates by 53%. These results show that the dissolved amino acids and dissolved carbohydrate fractions were preferentially decomposed compared with other fractions and are confirmed to be the labile fractions of dissolved organic matter. THE USE OF ALGAL ASSAYS AND CHLOROPHYLL CONCENTRATIONS TO DETERMINE FERTILITY OF WATER IN SMALL IMPOUNDMENTS IN WEST VIRGINIA,
West Virginia Univ., Morgantown. Dept. of Biology.
J. Davis, and J. Decosta.
Hydrobiologia, Vol 71, No 1/2, p 19-34, May, 1980. 14 Fig, 7 Tab, 26 Ref.

Descriptors: *Phosphates, *Algae, *Fertility, Eutrophic lakes, Lakes, Artificial lakes, Reservoirs, *West Virginia, Chlorophyll, *Nutrients, Nitrates, Phytoplankton, Eutrophication, Selenastrum capricornutum, Trophic level, Productivity, Phosphorus.

Phosphorus was the limiting nutrient in seven small artificial lakes in West Virginia, according to 21-day algal assay tests with Selenastrum capricornutum. In every case the water was fertile enough for algae to grow well without additional nutrients. All lakes were classified mesotrophic to slightly eutrophic. Sampling was done from December 20, 1975, to October 17, 1976, once each during the spring and fall isothermal periods and biweekly during summer stratification. Total phosphate-P (in micrograms per liter) ranged from 8.1 to 16.2 in spring, 2.18 to 69.9 in summer, and 8.4 to 29.4 in fall. Nitrate-N (in mg per liter) ranged from 0.038 to 0.720 in spring, 0 to 0.370 in summer, and 0.008 to 0.170 in fall. Uncorrected chlorophyll a values (in micrograms per liter) were 1.7 to 61.4 in spring, 4.3 to 232.0 in summer, and 4.5 to 24.5 in fall. (Cassar-FRC)
W82-00919

INORGANIC TRANSFORMATION OF APPLIED PHOSPHORUS IN BRACKISH WATER FISH POND SOIL UNDER DIFFERENT WATER SALINITY LEVELS,
Central Inland Fisheries Research Inst., Barrackpore (India).
G. N. Chattopadhyay, and L. N. Mandal.
Hydrobiologia, Vol 71, No 1/2, p 125-130, May, 1980. 6 Tab, 12 Ref.

Descriptors: *Phosphorus, *Fish ponds, *Salinity, Chemical reactions, Organic matter, Phosphates, *Brackish water, Ponds, Nutrients, Fertilizers, Aquatic soils.

Transformation of phosphorus, applied as 0 or 100 ppm KH_2PO_4, to brackish water fish pond soil was studied at different salinity levels (trace, 10, 20, and 30 ppt) and in the presence and absence of organic matter, a P-free starch. Added P disappeared rapidly from the water phase. For example, without added organic matter and at trace salinity, 44.40 ppm P present in the water phase on the tenth day of incubation decreased to 16.2 ppm on day 100; at 30 ppt salinity, 58.90 ppm P decreased to 13.80 ppm by day 100. Increases in water salinity produced increases in amount of saloid-bound P and decreases in Bray's No. 2 extractable form P. The transformation product in highest concentration was calcium phosphate, especially in more saline water. Lesser amounts of iron phosphate and aluminum phosphate were formed. Addition of organic matter did not affect the transformation of P into calcium phosphate but reduced fixation into the iron phosphate form, increasing the availability of P in water and soil phases. These results suggest that a more effective method of adding P to brackish water ponds would be split doses in combination with organic matter. (Cassar-FRC)
W82-00920

INFLUENCE OF PHOSPHORUS LOADS AND OF SOME LIMNOLOGICAL PROCESSES ON THE PURITY OF LAKE WATER,
Polish Academy of Science, Warsaw. Inst. of Ecology.
Z. Kajak.
Hydrobiologia, Vol 72, No 1/2, p 43-50, July, 1980. 8 Tab, 68 Ref.

Descriptors: *Phosphorus compounds, *Nutrients, *Water quality, *Lakes, Cycling nutrients, Nitrogen compounds, Fish, Agriculture, Eutrophication, Aquatic life, Zooplankton, Limnology, Phytoplankton, Algae, Surface water, Lake sediments, Sediments, Sedimentation, Biomass, Seston, Reviews.

The problem of the relationship between nutrient loads and phytoplankton biomass is reviewed with special emphasis on phosphorus. Total P concentrations in pollution sources vary from 1000 mg per liter in animal waste slurries to 0.01-0.1 mg per liter from atmospheric precipitation and natural forest and meadow runoff. Surfact nonpoint outflow from towns and runoff from bare soil contribute the most P to surface waters. The contribution of agriculture to eutrophication becomes proportionally more important as more facilities remove P from sewage in tertiary treatment. P in lake water is removed by retention in the sediment, but returns again to the epilimnion through water circulation and recycling by algae and other organisms. Fish affect nutrient concentrations by stirring up bottom sediments, eliminating sedimenting feces, releasing nutrients by metabolism, changing the species composition, intensifying the decomposition process, and changing light conditions. In fish ponds with common carp, the addition of silver carp increases the phytoplankton biomass and the rate of P sedimentation and decreases the amount of P released by the zooplankton. (Cassar-FRC)

PREDICTION OF PHOSPHORUS AND NITROGEN CONCENTRATIONS IN LAKES FROM BOTH INTERNAL AND EXTERNAL LOADING RATES,
University of East Anglia, Norwich (England). School of Environmental Sciences.
P. L. Osborne.
Hydrobiologia, Vol 69, No 3, p 229-233, March, 1980. 1 Fig, 2 Tab, 13 Ref.

Descriptors: *Lake restoration, *Phosphorus compounds, *Nitrogen compounds, Lakes, Nutrients, *Eutrophic lakes, Model studies, Seasonal variation, Prediction, Loading rates.

A variation of the Vollenweider model predicting phosphorus and nitrogen concentrations from loading rates was tested with data from a shallow, eutrophic lake, Barton Broad, 70 ha in area and 1 meter deep. Both external and internal loading occurred. Predicted and observed concentrations of P and N in the outflow were similar. Splitting the year into seasons overcame the problem of fluctuations in P and N loading rates (nutrient inputs from land drainage were higher in winter, and internal loading occurred in summer). The model can be used to predict the reduction in loading rate required either to limit phytoplankton population and improve water quality or to determine the nutrient concentrations suitable for reestablishing submerged macrophytes. (Cassar-FRC)

PHOSPHATE MODELS, A GAP TO BRIDGE,
Station Biologique de la Tour du Valat, Arles (France).
H. L. Golterman.
Hydrobiologia, Vol 72, No 1/2, p 61-71, July, 1980. 1 Fig, 3 Tab, 31 Ref.

Descriptors: *Model studies, *Phosphates, *Phytoplankton, Statistical models, Conceptual models, Nutrients, Lakes, Sedimentation, Adsorption, Productivity, Prediction, Loading rates.

Models for predicting phytoplankton productivity as a function of phosphate loading are necessary for water management. This paper discusses the differences between statistical models and dynamic or conceptual models and makes suggestions for bridging the gap between the two. In statistical models, formulas described the relationships between the P-loading and P-concentrations based on the statistical analysis of data derived from a population of lakes. In conceptual models, processes concerning P-dynamics are measured and formulas developed to describe these processes. The constants are then adjusted iteratively to achieve best fit. Conceptual models are difficult to extend to lakes other than those for which they were developed. The easier way to bring the two types of models closer together is to have correct statistical data on total sediment load, water hardness, productivity, rainfall, and other parameters. Then conceptual models can be used for sensitivity analysis and to provide information for further analysis of statistical models. Models based on fluxes have the greatest predictive value and make it easier to apply data from one lake to another. (Cassar-FRC)

REVIVING ACIDIFIED LAKES,
Uppsala Univ. (Sweden). Dept. of Limnology.
W. Rohde.
Ambio, Vol 10, No 4, p 195-196, 1981. 1 Fig, 8 Ref.

Descriptors: *Lake restoration, *Acidic water, *Neutralization, Rehabilitation, Lakes, Acidity, Acid rain, Algae, Bacteria, Water pollution effects, Water pollution treatment, *Sweden, Hydrogen ion concentration, Calcium carbonate.

The progressive acidification of lakes can be somewhat counteracted by the addition of neutralizing materials, but even very acid bodies of water are objects of natural colonization within a short time. Sweden has treated about 1000 lakes by adding calcium carbonate or other neutralizing materials, but the treatment is expensive and must be repeated. When the pH reaches 4 or 5, almost none of the original organisms are able to survive. Japan's volcanic lakes with pH's of 2-5 have existed long enough for acid-tolerant and acidophilic organisms to become established. These lakes include bacteria, fungi, algae, animals, macrophytes, and one species of fish. Thus, water devoid of life is the object of colonization, and research should be undertaken to determine the best autotrophic algae to introduce as pioneers. From naturally acid waters, plankton and benthic algae could be collected and studied, and eventually used to inoculate large bodies of water. At present, the only alternative is to apply neutralizing agents. (Small-FRC)

METHANE FORMATION IN THE ACID PEATS OF OKEFENOKEE SWAMP, GEORGIA,
Michigan State Univ., Hickory Corners. W. K. Kellogg Biological Station.
G. A. King, T. Berman, and W. J. Wiebe.
American Midland Naturalist, Vol 105, No 2, p 386-389, April, 1981. 2 Tab, 14 Ref.

Descriptors: *Methane, *Swamps, Methane bacteria, Peat, Peat bogs, Peat soils, Muck soils, Organic soils, Acidity, Acidic soils, *Okefenokee Swamp, Georgia.

Gas bubbles were collected at several sites in the Okefenokee Swamp in Georgia. Rates of methane production in peat samples were determined by first obtaining cores from the various Cooter Lake and Grant Prairie sites with 4-inch OD Plexiglas coring tubes. Analysis of the gas bubbles suggests that methanogenesis does occur in the Swamp despite the low pH. No apparent trend for lesser amounts of methane was evident among samples from sites with low pH at Cooter Lakes vs. the sites with higher pH at Lake Louise and Grassy Pond. The high content of methane in bubbles relative to carbon dioxide and the lesser solubility of methane indicates that bubbles in Okefenokee peat originate from a methane nucleus. In vitro studies revealed substantial rates of methane production. This production in the swamp could result in the formation of a major habitat, the floating peat batteries, and may be a significant source of methane to the atmosphere. A cycle of sinking-floating batteries controlled by bacterial activity may exist in the peat batteries of the swamp. (Baker-FRC)

MEAN SUMMER CIRCULATION IN LAKE ONTARIO WITHIN THE COASTAL ZONE,
Woods Hole Oceanographic Institution, MA.
G. T. Csanady, and J. T. Scott.
Journal of Geophysical Research, Vol 85, No C5, p 2797-2812, May, 1980. 8 Fig, 1 Tab, 21 Ref.

Descriptors: *Water circulation, Lakes, *Coastal waters, Lake shores, Flow characteristics, Flow profiles, Mathematical models, *Lake Ontario.

The mean flow pattern was observed in the well-resolved coastal zone of Lake Ontario during the summer (July 15 through August 15) of 1972. Detailed velocity and temperature profiles were used to define the summer circulation pattern. Simple equilibrium models of wind-driven flow were used to explain some of the features of the flow pattern. South shore mean currents behaved remarkably like the simple theoretical model of steady wind-driven flow in a two layer basin. North shore mean flow was completely different and lacked coastal jets. This was probably due to momentum (and heat) advection during full upwelling episodes. Thus, the south shore current pattern consisted of divergent coastal jets, the eastern shore had a deep current generated by interface friction below the strong coastal jets, and the northern shore return flow of warm water was probably accomplished at some distance offshore. THE EFFECT OF CHANGES IN THE NUTRIENT INCOME ON THE CONDITION OF LAKE WASHINGTON,
Washington Univ., Seattle. Dept. of Zoology.
W. T. Edmondson, and J. T. Lehman.
Limnology and Oceanography, Vol 26, No 1, p 1-29, January, 1981. 13 Fig, 11 Tab, 55 Ref.

Descriptors: *Phosphorus, *Nitrogen, *Eutrophic lakes, *Nutrients, Lakes, Lake sediments, Seasonal variation, Water pollution, Wastewater disposal, Eutrophication, *Lake Washington, Washington.

Variations in nutrient income resulting from alterations in sewerage arrangements have had a significant effect on the condition of Lake Washington. Between 1941 and 1963, the lake received increasing amounts of secondary sewage effluent from the Seattle, Washington, metropolitan area, with resultant changes in the amount of nutrients in the water and in the kind and quantity of phytoplankton. The lake responded quickly to declining inputs of effluent between 1963 and 1968, when almost all discharges to the lake were discontinued. The amount of nutrients, the quantity of phytoplankton, and the proportion of blue-green algae all decreased during this period. By 1975, the lake could be regarded as having recovered from eutrophication. Calculations of phosphorus and nitrogen income sewage to the lake had much more effect on the phosphorus regime than on the nitrogen regime. Total phosphorus input varied from a high of 204,200 kilograms per year in 1964 to a low of 42,900 in 1973 and 1976, with sewage contributing about 72 percent of the total in 1962. Variation in total nitrogen ranged from a high of 1,419,000 kilograms per year in 1964 to 734,000 in 1976. Seasonal differences were found in the deposition of phosphorus to and release from the sediments. On the average, the sediments retained about 57 percent of the income over the long term. After diversion of the sewage effluent from the lake, there was a slight increase in the proportion of incoming phosphorus lost to the sediments. The amount of phosphorus lost permanently to the sediments during a year was found to be more closely related to the annual income than to the mean concentration in water. (Carroll-FRC)

A METHOD FOR THE EVALUATION OF CONDITIONS IN A FISH POND SEDIMENT,
Science and Education Administration, Durant, OK. Southern Plains Watershed and Water Quality Lab.
Y. Avnimelech, M. Lacher, A. Raveh, and O. Zur.
Aquaculture, Vol 23, No 1-4, p 361-365, April, 1981. 2 Tab, 6 Ref.

Descriptors: *Bottom sediments, *Fish ponds, *Ecosystems, Phosphorus, Sediments, Organic matter, Fish, Decomposing organic matter, Anaerobic conditions, Measurement techniques.

Intensive fish farms are known to suffer significant decreases in fish growth and increases in the yield coefficient over time. This decline in fish pond fertility with time appears to result from excessive and rapid accumulation of organic carbon and nitrogen compounds in the fish pond sediment, which can cause a reduction in the oxidation potential. Although the rate of fish growth is commonly used to evaluate conditions in the fish pond, it is hard to relate fish growth to the conditions in the sediment at a given time using this method. A method for measuring fish grazing in the sediment has been developed to assist evaluation of the overall conditions in the sediments at a given time. The method involves measuring the extent of grazing of fish at the sediment by counting the phosphorus-32 tagged mud in the digestive tract of fish. The method was tested using two types of sediments (fresh soil and soil which had previously been used in intensive aquaculture systems for about 100 days) and three treatments with nutrient pellets (none, 60 grams, and 100 grams). In the control experiments, nets prevented the fish from grazing. Analysis of the uptake of the tagged mud by the fish showed that the uptake of phosphorus-32 by fish in containers with fresh soil without added nutrients was only slightly higher than the uptake of the tagged mud in the control treatment, which was not negligible. Fish in containers with fresh soil enriched with nutrients had the highest phosphorus-32 uptake. Fish in containers with enriched aged fish pond sediments, which were overloaded and anaerobic, showed phosphorus-32 uptakes which were about one third less than those in the enriched fresh soil. This method is shown to yield consistent results which are in agreement with previous experiences and observations of the fish growth in intensive ponds. (Carroll-FRC)

THE EFFECT OF CONTINUOUS ADVANCED WASTEWATER TREATMENT BY THE CITY OF SPOKANE ON THE TROPHIC STATUS OF LONG LAKE, WA DURING 1979.
Eastern Washington Univ., Chemey. Dept. of Biology.
State of Washington Department of Ecology, Olympia, Document DOE 80-11, October, 1980, 86 p. 18 Fig, 25 Tab, 34 Ref.

Descriptors: *Mesotrophic lakes, Mesotrophy, *Trophic level, *Lakes, Water quality management, *Wastewater treatment, Phosphorus removal, Chlorophyll A, On-site data collections, Hydrologic data collections, Phytoplankton, Phosphates, Water quality, *Long Lake, Reservoirs, Spokane River, *Washington.

The water quality of Long Lake, an impoundment of the Spokane River, was documented in a study conducted during the second year of operation of an advance wastewater treatment facility (AWT) built by the City of Spokane in 1977. Long Lake was found to exhibit mesotrophy, as it had in a study conducted in 1978. Phosphorus removal from the sewage effluent resulted in significantly lower phosphate loads to the reservoir than before the AWT was implemented. Phytoplankton biovolumes were also reduced. Correlations showed that chlorophyll A concentrations gave a reasonable estimate of phytoplankton standing crop. In addition, areal phosphorus loading gave an excellent estimate of mean chlorophyll A concentration. The successional patterns of the major zooplankters were similar to those observed in 1978 and prior to the AWT. Zooplankton standing crops were less dense than those determined before the AWT, possibly the result of decreased food availability. Analysis of variance and least significant difference statistical evaluation showed that mean daily total and orthophosphate loads in 1979 at the AWT sewage effluent (S.E.) sampling station were significantly lower than those prior to AWT, but not from those determined in 1978. The sewage outfall effected an increase of total inorganic nitrogen and orthophosphate concentrations in the river of 1.6 and 2.5 times, respectively. (Garrison-Omniplan)

AN ASSESSMENT OF THE TROPHIC STATUS OF DEER, LOON, AND DIAMOND LAKES,
Washington State Dept. of Ecology, Olympia.
L. Singleton, J. Thielen, and D. Kruger.
Document DOE 80-9, July 1980. 33 p. 13 Fig, 12 Tab, 26 Ref, 3 Append.

Descriptors: *Trophic level, Mesotrophy, *Lakes, *Mesotrophic lakes, *Water pollution effects, Pollution effects, Eutrophication, Oxygen depletion, Water quality, Water quality standards, Data collection, On-site data collections, Hydrologic data collections, Deer Lake, Loon Lake, Diamond Lake, *Washington.

The trophic status of Deer, Loon, and Diamond Lakes, located north of Spokane, Washington, was evaluated during the 1978 growing season. Sampling occurred bi-weekly from May to November. Historical data were also utilized to determine if water quality had changed in any of the lakes. The results indicated that all three lakes are mesotrophic, each having nutrient and chlorophyll A concentrations below the levels established for eutrophic waters. All three lakes experience some degree of hypolimnetic anoxia, with Loon Lake the most anoxic. Deer Lake has the fewest water quality problems of the three, and the least amount of hypolimnetic oxygen depletion. Deer Lake appears able to sustain its present trophic condition longest and therefore should probably be the last of the three lakes sewered. Diamond and Loon Lakes both have some water quality problems which indicate they are not as stable. Loon Lake showed a significant decrease in water clarity and a significant decrease in the mean secchi disk depth. The anoxia observed in Diamond Lake was not as severe as in Loon Lake; however, it is still noteworthy. The water quality of Diamond Lake appears to be spatially affected by sludge beds present from previous log rafting practices. The sewering of Loon and Diamond Lakes needs further evaluation utilizing current demographic and land usage trends present at each lake. Conditions seem to have changed little since the DOE study in 1973; another study is recommended for 1983. (Garrison-Omniplan)

GONAD DEVELOPMENT, FECUNDITY, AND SPAWNING SEASON OF LARGEMOUTH BASS IN NEWLY IMPOUNDED WEST POINT RESERVOIR, ALABAMA-GEORGIA,
Alabama Cooperative Fishery Research Unit, Auburn.
T. J. Timmons, W. L. Shelton, and W. D. Davies.
Technical Papers of the U.S. Fish and Wildlife Service. No 100, 1980. 8 p. 2 Fig, 2 Tab, 28 Ref.

Descriptors: *Reservoir fisheries, *Bass, *Spawning, *Seasonal distribution, *Fish eggs, Fish populations, Fish establishment, Mature growth stage, Environmental effects, *West Point Reservoir, Alabama, Georgia.

After the filling of a new reservoir provides a large area and volume of water for fish population expansion, largemouth bass usually thrive for the first 3 to 10 years, after which growth rate slows. Little is known about the fecundity and sexual maturity of the early year classes of fast-growing largemouth bass in reservoirs in the southeast. West Point Reservoir, an impoundment of the Chattahoochee River, was impounded in October 1974 and filled to full power pool by May 1975. Because high turbidity precluded observation of nest-building and spawning, the spawning period was determined by observing the frequency distribution of ovarian egg diameters and calculating gonosomatic indices. The percentage of body weight contributed by the ovaries and frequency distributions of ovarian egg diameters were reliable indicators of the spawning season of the largemouth bass in the reservoir in 1977. Spawning began in mid-April and continued until mid-June. Some fish apparently spawned more than once, but no summer or fall spawning was indicated. Individual fecundity, determined by a dry weight method, ranged from 6,232 to 117,241 mature eggs for fish over 300 mm in total length. Eggs matured at a size larger than those described in other studies of largemouth bass. The fast-growing initial year classes (1975 and 1976) of largemouth bass dominated the reproducing population. THE IMPACT OF A NATURAL DRAWDOWN ON THE GROWTH OF FOUR EMERGENT SPECIES IN A PRAIRIE GLACIAL MARSH,
Iowa State Univ., Ames. Dept. of Botany and Plant Pathology.
A. G. Van der Valk, and C. B. Davis.
Aquatic Botany, Vol 9, No 4, p 301-322, December, 1980. 6 Fig, 5 Tab, 20 Ref.

Descriptors: *Marshes, *Drawdown, Water level, Drought, *Aquatic plants, Vegetation, *Ecological effects, *Eagle Lake, Iowa.

The impact of a natural drawdown in 1977 on the growth of four dominant emergent species at Eagle Lake, Iowa was investigated. Three of the species (Scirpus validus Vahl, Sparganium eurycarpum Engelm. and Typha glauca Godr.) dominate the polydominant communities of the cyclic zone of the Lake. S. eurycarpum and T. glauca also grow in monodominant communities in the non-cyclic zone. Scirpus fluviatilis Gray is found only in small monodominant stands in the non-cyclic zone. Growth of the three species was severely hampered by the drought. The drought, however, reversed a decline in vigor which had started before the drought in Scirpus validus Vahl. The drought enabled this species to exist in the marsh for two more years. The data suggest that periodic drawdowns enable several emergent species to coexist in a community due to their diverse responses to the disturbance. (Baker-FRC)

2I. Water In Plants

TRANSPIRATION, STOMATAL CONDUCTANCE, AND PHOTOSYNTHESIS OF TOMATO PLANTS WITH VARIOUS PROPORTIONS OF ROOT SYSTEM SUPPLIED WITH WATER,
Department of Agriculture, Harrow (Ontario).
C. S. Tan, A. Cornelisse, and B. R. Buttery.
Journal of the American Society for Horticultural Science, Vol 106, No 2, p 147-151, March, 1981. 3 Fig, 4 Tab, 14 Ref.

Descriptors: *Tomatoes, *Root development, *Irrigation requirements, Plant growth, Water requirements, *Transpiration, Photosynthesis, Stomatal transpiration, Soil moisture, Water conservation, Agriculture, Water stress, Soil water.

Tomato (Lycopersicon esculentum Mill.) plants were grown in sectional boxes so that each quadrant of the root system could be watered separately. Withholding water from 1 or 2 quadrants did not reduce transpiration, photosynthesis, stomatal conductance, or leaf surface area, suggesting that the absorption capacity of the tomato roots increased in response to the transpirational demand. The shoot:root ratio of the plants increased as the proportions of roots supplied with water increased, 18.4 at 25% watered to 27.9 at 100% watered. Withholding water from 25, 50, and 75% of the root system for two weeks, followed by full watering caused no apparent damage to the root systems in the dry quadrants. Transpiration (1.98-2.45 kg per day), photosynthesis (8.7-10.6 mg per sq dm per hour), and stomatal conductance (0.19-0.24 cm per sec) recovered fully. These results suggest that there is no need to irrigate the entire root system. (Cassar-FRC)

WATER RELATIONS OF THREE COWPEA CULTIVARS (VIGNA UNGUICULATA L.),
Ibadan Univ. (Nigeria). Dept. of Agronomy.
O. Babalola.
Plant and Soil, Vol 56, No 1, p 59-69, 1980. 3 Fig, 3 Tab, 14 Ref.

Descriptors: *Water stress, *Growth rates, *Crop yields, Soil water, Roots, Water use efficiency, Evapotranspiration, Cowpea, *Nigeria, Soil-water-plant relationships.

Three cowpea cultivars were investigated to determine the effect of water stress at different growth stages with respect to floral abscission and other growth parameters. Root system development and soil moisture extraction patterns were determined, and water use efficiency under dryland farming was investigated. Soil moisture stress significantly reduced growth and yield (34-46%) of all three. For Ife Brown variety, a semi-erect type, grain yield reduction was highest when stress was imposed at flowering/podding stages. There was no reduction in yield for New Era, a spreading type. Ife Brown was most sensitive to decreased matric potential, and New Era exhibited the highest formal abortion. Evapotranspiration was higher for New Era and Ife Brown than for Adzuki, an erect type. Water use efficiency was highest for New Era and least for Adzuki. New Era may not be suitable for intercropping, but Ife Brown may be popular because its drought susceptibility is intermediate. THE EFFECT OF TEMPERATURE ON SALT UPTAKE BY TOMATO PLANTS WITH DIURNAL AND NOCTURNAL WATERLOGGING OF SALINIZED ROOTZONES,
Victorian Dept. of Agriculture, Ferntree Gully (Australia). Scoresby Horticultural Research Station.
D. W. West, and J. A. Taylor.
Plant and Soil, Vol 56, No 1, p 113-121, 1980. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Temperature effects, *Salinity, *Accumulation, *Tomatoes, Waterlogging, Root zone, Roots, Sodium chloride, Sodium ions, Chloride ions, Compairson studies.

Tomato plants were grown at three temperatures with the rootzones of half the plants waterlogged for the day or night period of each 24 hours. Other plants were grown with drained rootzones, and all plants were irrigated with saline (0.09 M NaCl) nutrient solution. Increase in temperature resulted in increases in leaf Na-ion and Cl-ion concentrations in plants with drained rootzones. In waterlogged plants, the maximum leaf concentration of the ions occurred at 20C. There were no differences in ion concentrations at 10C between drained and waterlogged rootzones. Waterlogging of the rootzones resulted in higher concentrations of ions in leaf and stem tissues at 20 and 28C. No differences were found in the Na and Cl ions in plant tops when plants were waterlogged during the day or night. As temperature increased, transpiration increased, but no other treatment dependent responses were noted. Thus, the direct importance of temperature of growth on the interaction between salinity and waterlogging was demonstrated. (Small-FRC)

MOISTURE TRANSPORT IN A SOIL-PLANT SYSTEM: A MATHEMATICAL MODEL AND FINITE ELEMENT ANALYSIS,
Weyerhauser Co., Centralia, WA.
P. Farnum, and G. F. Carey.
Advances in Water Resources, Vol 4, No 2, p 67-76, June, 1981. 10 Fig, 1 Tab, 26 Ref.

Descriptors: *Soil-water-plant relationships, *Mathematical models, *Water transport, Plant water potential, Soil water, Evapotranspiration, Finite element method, Mathematical studies.

A comprehensive integrated model was developed for the mathematical analysis of moisture transport from the soil through an individual plant to the atmosphere. The important features associated with non-linear time-dependent diffusion in a non-homogeneous soil are incorporated, including local flow to the individual roots. The flow system is modeled by modeling separate flow subsystems. The model and analysis were used to assess given environmental conditions and to assist in establishing planting guidelines in reforestation. The model's intrinsic value lies in hypothesis testing, including the proposed improvement or elaborations on particular local features. Also, models of the soil-plant system can be incorporated and their effect on the entire system determined. Model predictions compared well with actual experimental results. (Small-FRC)

THE EFFECT OF HEIGHT OF WATER TABLE ON THE GROWTH OF HOLCUS LANATUS WITH REFERENCE TO LOLIUM PERENNE,
Oxford Univ. (England). Dept. of Agricultural Science.
T. A. Watt, and R. J. Haggar.
Journal of Applied Ecology, Vol 17, No 2, p 423-430, August, 1980. 6 Fig, 1 Tab, 15 Ref.

Descriptors: *Soil-water-plant relationships, *Plant growth, *Water table, Water level, Soil water table, Experimental data.

Plants of Holcus lanatus L. and Lolium perenne L. occur frequently in wet sites. They invade sown areas earlier and spread more rapidly on heavy, poorly drained sites. Plants of the two weeds were grown in monocultures and in 50:50 mixtures in free-draining conditions and with water table levels of 5, 11, or 21 centimeters below the soil surface in an effort to determine the effects of depth of the water table on their growth. At the first harvest all three stand types produced the highest yields with the lowest water table, with yields decreasing with increasing height of water table. At subsequent harvest, the free-draining treatment resulted in the highest yields. The absence of significant species times stand type and stand type times water table interactions indicate that there was no difference between the effects of interspecies or intraspecies competition. There was no significant difference between the percentage nitrogen contents of the two grasses in monocultures, with increasing water table height resulting in lower concentrations of nitrogen in both species. While L. perenne did not produce surface roots, coverage of the soil surface by surface roots of H. lanatus ranged from 15% in free-draining soil to 83% in the high water table treatment. There was also an increase in the number of nodes producing roots in H. lanatus with increasing height of water table. These results indicate that adaptations made

by the H. lanatus plant when growing in soil with a high water table may contribute to their long-term survival at the expense of short-term shoot production. (Carroll-FRC)

ANNUAL PLANT PRODUCTION-PRECIPITATION RELATIONS IN ARID AND SEMI-ARID REGIONS,
Botanical Research Inst., Pretoria (South Africa).
M. C. Rutherford.
South African Journal of Science, Vol 76, No 2, p 53-56, February, 1980. 1 Fig, 35 Ref.

Descriptors: *Crop production, *Rainfall rate, Productivity, Precipitation intensity, *Semiarid lands, *Arid lands, Semiarid climates, Climates, Water stress, Mathematical studies.

An attempt is made to appraise published relations between annual precipitation and annual plant community production for arid and semi-arid areas. In many cases formulas used are not suitable for these areas. Usually their unsuitability is due to a lack of supporting data or such other reasons as the arbitrary extrapolation of results from short intervals of a growing season over longer periods, the integration of the moisture regime with other important environmental factors, the assumption of linear or identity relations between moisture regime and production, and the limitation of the prediction to only part of the potential plant production. Discussion is given of Walter's relation, in which mean annual precipitation is related to above-ground herbaceous production for semi-arid areas of South West Africa. Discussion is also given to Rosenzweig's and Lieth's relations. The Rosenzweig curve relates annual actual evapotranspiration and above-ground plant production over a much greater range of annual precipitation than Walter's equation. Lieth's Miami Model and the C. W. Thornthwait Memorial Model both predict total production above and below ground. It is concluded that future work in this field would benefit from a clear definition of the term 'production,' objective sampling, full presentation of the data, inclusion of other climatic variables to help refine production relations and improve levels of predictability, and adequate testing of available relations before application, with the derivation of new relations where necessary. W82-00693

GROWTH AND NITROGEN FIXATION OF AESCHYNOMENE UNDER WATER STRESSED CONDITIONS,
Florida Univ., Gainesville. Dept. of Agronomy.
S. L. Albrecht, J. M. Bennett, and K. H. Quesenberry.
Plant and Soil, Vol 60, No 2, p 309-315, 1981. 1 Fig, 3 Tab, 23 Ref.

Descriptors: *Water stress, *Nitrogen fixation, *Tropical regions, Waterlogging, Drainage, *Legumes, Soil properties, Soil porosity, Soil moisture retention, Flooding, Nitrogen, Soil moisture deficiency, Moisture deficiency, Plant growth, *Aeschynomene, Soil-water-plant relationships.

The tolerance of nitrogen fixation was studied in several accessions of Aeschynomene americana in response to various levels of soil moisture. The accessions of A. americana were subjected to periods of flooding or soil water deficits to determine stress effects on nitrogen fixation. Cuttings of 22 field grown accessions were rooted in sand and transplanted to a mixture of Wauchula sand, peat and perlite in pots. Nitrogenase activity was determined by the acetylene reduction assay. Both flooding and drought treatments showed increased root weights. The flooding treatment did not significantly reduce nodule weight, percent nodulation, or nitrogenase activity, whereas soil moisture deficits caused reductions in these variables. Many of the accessions have effective mechanisms for maintaining active nodules under flooded conditions. Flooded plants maintained leaf water, osmotic and turgor potentials which were similar to those of the well-watered controls. Droughted plants appeared to have much lower nodule water potentials. Flooded plants maintained leaf water relationships which were slightly more favorable than those of the well-watered controls, although the differences were small. It is not known which factors specifically allow waterlogged A. americana to fix nitrogen. Accessions which showed good growth and nitrogen fixation under flooding in the greenhouse will be tested on seasonally waterlogged areas to measure performance in the field. (Baker-FRC)

WATER DYNAMICS IN THE SOIL-PLANT-ATMOSPHERE SYSTEM,
Science and Education Administration, Temple, TX. Grassland, Soil and Water Research Lab.
J. T. Ritchie.
Plant and Soil, Vol. 58, No. 1-3, p 81-96, 1981. 4 Fig, 34 Ref.

Descriptors: *Soil-water-plant relationships, *Agriculture, *Soil water, *Crop production, Atmospheric pressure, Transpiration, Mathematical models.

Water dynamics in the soil-plant-atmosphere system are determined by the capacity of the soil water reservoir, its depletion and replenishment, and its efficient management for crop production. Water balance calculations using computers provide a means for accurate estimations of crop yields, early warning about food shortages, and reliable irrigation scheduling and water resource planning. Reliable water balance evaluations depend upon accurate estimation of evaporation from soil and plants. Incomplete crop canopy or a deficiency of water in the root zone may cause a discrepancy between actual evaporation and maximum evaporation. Since it is almost impossible to generalize about plant response to water deficit using soil measurements, attention has been focused on the use of plant measurements for this parameter. Physical measurements sensitive to crop water deficit include plant stomatal resistance and plant water potential. However, both of these measurements are difficult to utilize for operational purposes. Accurate water balance modelling also requires estimation of the amount of water infiltration into the soil from precipitation or irrigation, which can be accomplished using either physical models of hydrologic processes or statistical models fitted to experimental data. (Carroll-FRC)

TEMPERATURE AND WATER RELATION PATTERNS IN SUBALPINE UNDERSTORY PLANTS,
Wyoming Univ., Laramie. Dept. of Botany.
W. K. Smith.
Oecologia, Vol 48, No 3, p 353-359, 1981. 6 Fig, 1 Tab, 30 Ref.

Descriptors: *Plant growth, *Water requirements, Transpiration, Mountains, Cold regions, Water stress, *Temperature effects, Forests, Rocky Mountains.

A comparison was made of the temperature and water relations of seven understory species that are abundant and grow sympatrically in the understory of the coniferous forests of the Rocky Mountains. Several general characteristics in the water relations of the seven species emerged. Soil moisture remained relatively high throughout the summer even though minimum plant xylem water potentials commonly decreased below minus 1.0 MPa, especially for the more shallow rooted herbaceous species. Leaf temperatures and conductances rose sharply during exposure to sunflecks, along with corresponding increases in transpiration and decreases in xylem water potentials. Midday wilting occurred for four of the seven species, all of which were herbaceous. Turgor was regained fairly rapidly during subsequent shade periods. Stomata on either leaf surface appeared to remain fully open when oriented away from direct sunlight. The stomatal opening in the morning occurred rapidly for sunlit leaves compared to a more gradual opening for plants in the shade. The amount of incident light on abaxial surfaces was not sufficient to cause full stomatal opening. The study indicated that midday wilting may be a common understory phenomenon within coniferous forests in the Rocky Mountains. Apparently, either water uptake from the soil or water transport from the roots to the leaves was not sufficient to support the transpiration demand for these herbaceous species, in contrast to the two species which were more deeply-rooted, and shrubby in nature. WATER STATUS OF SOIL AND VEGETATION IN A SHORTGRASS STEPPE,
Colorado State Univ., Fort Collins. Natural Resource Ecology Lab.
O. E. Sala, W. K. Lauenroth, W. J. Parton, and M. J. Trlica.
Oecologia, Vol 48, No 3, p 327-331, 1981. 6 Fig, 17 Ref.

Descriptors: *Vegetation, *Soil water, Moisture stress, Water stress, Water loss, Water supply, Water shortage, Water scarcity, Water deficit, Moisture availability, *Steppes, North America, Soil-water-plant relationships, Semiarid climates, Plant growth, Available water.

Patterns of water availability were investigated in the semiarid shortgrass steppe region of North America. Specifically, attempts were made to describe the status and transfers of water among the soil-plant-atmosphere compartments during a drying cycle, the pattern of water losses from a completely wet soil profile, and how some physiological plant variables were affected throughout a drying cycle. The study site was on the piedmont or northcentral Colorado at Pawnee Site, about 61 km northeast of Fort Collins. Principal perennial species on the study site were blue grama, fringed sagewort, plains pricklypear, and needleleaf sedge. Plant and soil water measurements were taken on 15 dates during a 56 day dry cycle. At the beginning of the cycle, water loss occurred exclusively from the top layer. After that the next deeper layer also began contributing water to the total loss. Sixteen days passed before water potential values significantly different from zero were recorded in the 15 cm depth layer. In the deepest layer, 60 cm, water loss began to occur 39 days after the start of the study. Through the first 50 days of plant growth, leaf conductance and water potential at noon slowly declined. After 50 days these levels decreased rapidly. The predawn water leaf potential remained unchanged during the first 45 days, decreasing rapidly thereafter. Predawn leaf water potentials were highly correlated with water potentials of the wettest layer. It appeared that the root surface area limited the water flow through an important part of the day in this semiarid ecosystem. Axial root resistance did not appear significant in determing equilibrium status between leaves and the wettest soil layer. (Baker-FRC)

COMPARATIVE FIELD WATER RELATIONS OF FOUR CO-OCCURING CHAPARRAL SHRUB SPECIES,
San Diego State Univ., CA.
S. W. Roberts, P. C. Miller, and A. Valamanesh.
Oecologia, Vol 48, No 3, p 360-363, 1981. 4 Fig, 18 Ref.

Descriptors: *Water requirements, *Plant growth, Seasonal variations, *Chaparral, Shrubs, Water potentials, Drought, Water shortage, Moisture stress, Water stress.

Seasonal water use patterns were investigated in chaparral shrubs using the null-balance approach and evaluating the method with regard to previous measurements of water use patterns in these same shrubs. Field measurements of xylem pressure po-

tential and leaf conductance were made through a summer drought cycle of Adenostoma fasciculatum, Ceanothus greggi var perplexens, Quercus dumosa, and Arctostaphylos glauca, from June through November 1978 at Echo Valley, California. Progressive drought development was noted over the seasonal courses of minimum water potential measurements, with a further clear seasonal segregation by species becoming evident. Maximum conductances showed differences between species, and in A. fasciculatum there were further differences by leaf age class. No differences in maximum conductances between old and new leaves of A. glauca were noted; in general this plant showed the lowest maximum conductances. A peak in October of maximum conductance was noted in association with a short period of precipitation. Diurnal variation of water potential-leaf conductance relations showed large hysteresis early in the season for A. fasciculatum leaves on the equator-facing slope. The hysteresis decreased as the drought progressed. These findings suggest that early in the season the water is available to the shrubs and therefore stomatal behavior is largely governed by a complex array of environmental factors. Late in the season, however, stomatal behavior becomes increasingly dominated by tissue water status. (Baker-FRC)

THE EFFECT OF ENVIRONMENTAL UNCERTAINTY ON MORPHOLOGICAL DESIGN AND FLUID BALANCE IN SARRACENIA PURPUREA L.,
Stanford Univ., CA. Dept. of Biological Sciences.
J. Kingsolver.
Oecologia, Vol 48, No 3, p 364-370, 1981. 10 Fig, 17 Ref.

Descriptors: *Water potentials, *Plant morphology, *Pitcher plant, Leaves, Evaporation, Precipitation, Drying, Rainfall, Simulation, Model studies.

The morphological design of pitcher plant leaves was considered with respect to their fluid balance in variable environments. Leaves of different sizes and geometries were compared with respect to fluid loss and fluid gain rates. Responses of these different geometries to variations in the hydric environment were analyzed. General design principles were sought in variable and unpredictable environments, with the aim of finding the leaf shape which minimizes the probability that the leaf will lose all of its fluid at any time. The major components of the leaf fluid balance were taken to be precipitation and evaporation, with all other components neglected for the predictions of leaf fluid levels. The temporal distribution of rainfall at the study area is highly non-uniform, with no measurable precipitation occurring on 62% of all days, and with less than 1.0 cm/day falling on 75.5% of the days on which precipitation fell. While no single design criterion can determine the morphology of an organism, it became increasingly clear that continual maintenance of positive fluid balance may be a relevant design criterion for leaf geometry. In terms of both shape and leaf size, the pitcher leaf of Sarracenia purpurea is indeed an effective design for reducing desiccation frequency. Desiccation is related not to the mean but to the variation in fluid volume during the season. The pitcher leaf integrates meteorological information over the time period which corresponds closely to the temporal distribution of variation in rainfall. The leaf thus acts as a low-pass filter which selectively removes the high frequency components of rainfall variation. (Baker-FRC)

PLANT-WATER RELATIONS AND ADAPTATION TO STRESS,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Plant Industry.
N. C. Turner, and J. E. Begg.
Plant and Soil, Vol 58, No 1-3, p 97-131, 1981. 6 Fig, 2 Tab, 180 Ref.

Descriptors: *Water stress, *Soil-water-plant relationships, Water deficit, Crop yield, Crop production, Plant morphology, *Plant growth, Plant physiology, Soil water, Evaporation, Rainfall, Literature reviews.

Water deficits affect the growth and yield of plants in many ways. While dramatic increases in yields of cereals have been experienced in areas having a regular supply of water assured through rainfall or irrigation, arid and semi-arid regions have experienced much smaller increases over the past 40 years. Improved varieties and higher fertilizer use are not as effective in increasing yields in water-limited environments as they are in more temperate regions or in areas in which irrigation can be provided. Large year-to-year variations in rainfall in Mediterranean-type environments also result in large year-to-year variations in yield per unit area. In order to achieve crop increases in cereal production in semi-arid areas, crops must be designed for adversity, particularly a limited and variable water supply. The development of crop water deficits, and the responses of plants to these deficits, are described. Plants possess a variety of developmental, morphological, and physiological mechanisms which enable them to adapt to water deficits. Rapid phenological development after germination has been widely adopted for crops in semi-arid environments. Developmental plasticity is also highly desirable for crops in these areas. Physiological mechanisms which enable plants to adapt to water stress include seed priming, stomatal control of water loss, osmotic adjustment, and cellular tolerance of dehydration. In order to improve the grain yield of crops in a Mediterranean-type environment, it is necessary to increase the water passing through the crop in transpiration, increase the water use efficiency, and/or increase the proportion of total dry matter going to the grain. While the agronomist works to ensure that the most efficient use is made of available water, the breeder must try to produce a cultivar that will give a greater yield under water-limited conditions. CLONAL VARIATIONS IN THE WATER RELATIONS OF RED OSIER DOGWOOD DURING COLD ACCLIMATION,
Minnesota Univ., St. Paul. Lab. of Plant Hardiness.
E. A. Bray, and L. R. Parsons.
Canadian Journal of Plant Science, Vol. 61, No. 2, p 351-363, April, 1981. 8 Fig, 2 Tab, 16 Ref.

Descriptors: *Cold regions, *Acclimatization, *Trees, *Dogwood, Moisture availability, Water use efficiency, Variability.

Studies were made to determine if red osier dogwood acclimating to cold under natural photoperiod and temperature undergoes changes in water relations similar to those demonstrated in plants acclimated in growth chambers and to determine if water relations account for differences in hardiness of several climatic races of red osier dogweed. Cuttings were taken from plants in the University of Minnesota arboretrum and field plots. The races of dogwood could be divided into two groups: Oregon, Idaho and Montana varieties became hardy to between -25 and -30 degrees C, and Alaska, North Dakota and Washington varieties became hardy to between -37 and -42 degrees C. After the initial frost, daytime stomatal resistance increased first in the Alaska clone and then in the Washington, Montana and North Dakota clones, but not in Idaho and Oregon clones. The remaining water relations parameters measured did not show differences among the races of dogwood. Stem water content of all clones decreased into mid-October, when they reached a similar water content of about 1 g water/g dry weight. Midday leaf xylem pressure potential of all clones increased during acclimation. Relative water content of the stems decreased during acclimation, but later increased. The water relations parameters of the outdoor acclimation process were very similar to those reported for growth chamber studies. Thus it was concluded that dogwood races from various natural locations acclimated at different rates in a common field location. (Baker-FRC)

SOME ASPECTS OF PLANT WATER RELATIONS IN ALASKAN ARCTIC TUNDRA SPECIES,
San Diego State Univ., CA.
S. Oberauer, and P. C. Miller.
Arctic and Alpine Research, Vol. 13, No. 2, p 205-218, May, 1981. 1 Fig, 5 Tab, 21 Ref.

Descriptors: *Plant water potential, *Tundra, *Alaska, *Arctic, Water potentials, Polar regions, Arctic zone, Cold regions.

Four sites including a snow patch, a south facing slope, a north facing slope, and a tussock tundra ridge were selected for water availability measurements in arctic and alpine tundra. Xylem pressure potentials and interrelations between relative water content, xylem pressure potential, and leaf conductance of several species which are common in tussock and montane tundra were compared at these four Alaskan sites in 1977 and 1978. Evergreen shrubs were found to have the lowest leaf conductances, graminoids and forbs the highest. The relations between relative water content, xylem pressure potential and leaf conductance were not unique to a growth form nor to a vegetation zone. Although different species attained different minimum pressure potentials, individuals of a species showed similar potentials in a variety of sites. The narrow range of minimum potentials of a species and the similar behavior of species within a site indicate strong selection segregating species. (Baker-FRC)

WATER STRESS AND COLD HARDINESS IN FIELD-GROWN CITRUS,
Florida Univ., Gainesville. Dept. of Fruit Crops.
F. S. Davies, D. W. Buchanan, and J. A. Anderson.
Journal of the American Society for Horticultural Science, Vol. 106, No. 2, p 197-200, March 1981. 2 Fig, 1 Tab, 24 Ref.

Descriptors: *Citrus fruits, *Frost protection, *Irrigation effects, Water stress, Oranges, Fruit crops, Crop yield, Orchards, Trees, *Florida.

The treatment which permitted the least frost damage in Orlando tagelo (Citrus reticulata Blanco x Citrus paradisi Macf.) trees was no fall irrigation and under-tree sprinkling during a frost; leaf drop was 11.5% and undamaged fruit, 60%, following a frost in December 1979, in wich leaf temperature remained below -3.9C for 8 hours. Trees suffered the worst damage with fall irrigation and no sprinkling during frost. Intermediate damage was allowed by fall irrigation plus frost irrigation and no fall irrigation plus no under-tree sprinkling. Although the soil moisture content of irrigated blocks was significantly greater than for non-irrigated blocks during fall, afternoon leaf xylem water potentials and stem water contents were comparable. INVESTIGATIONS OF CONTROL MECHANISMS OF GERMINATION UNDER WATER STRESS,
Department of Agriculture and Fisheries for Scotland, Edinburgh.
T. W. Hegarty, and H. A. Ross.
Israel Journal of Botany, Vol 29, No 1-4, p 83-92, 1980/1981. 2 Fig, 4 Tab, 17 Ref.

Descriptors: *Water stress, *Germination, *Water potentials, *Plant growth substances, Seeds, Plant

growth, Plant physiology, *Plant water potential, Planting management.

Seedling growth immediately after germination was able to proceed at water potentials lower than those that permitted germination in most varieties of seeds studied. This differential could be reduced by growth regulators, which made the water potential of seed germination more negative. The difference was eliminated by a combination of ethrel and kinetin in red clover and lucerne. Evidence suggests that the process in germination most sensitive to water stress is the initiation of cell elongation. The differential sensitivity to moisture stress is suggested as a form of dormancy. This control mechanism shows variations in operation and response to external stimuli and depends on genetic and environmental factors. (Cassar-FRC)

PHOTOSYNTHESIS AND GROWTH IN POPULATIONS OF POPULUS DELTOIDES FROM CONSTRATING HABITATS,
Illinois Univ. at Urbana-Champaign. Dept. of Botany.
A. B. McGee, M. R. Schmierbach, and F. A. Bazzaz.
American Midland Naturalist, Vol 105, No 2, p 305-311, April, 1981. 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Plant growth, *Habitats, Floodplain, Drought, *Soil types, Transpiration, Trees, Respiration, Photosynthesis, *Soil-water-plant relationships, *Populus deltoides.

The degree and expression of ecological differentiation among populations of Populus deltoides from three contrasting habitats were examined. The influence of some edaphic conditions upon growth, photosynthesis and transpiration in these populations was investigated. Ramets of floodplain, strip-mine and sand-dune origin were grown in soils of each locality and growth parameters were measured for representative members of each population. The photosynthetic response of flooded and droughted individuals in their native soils was investigated. While the populations were different in some responses, they all accumulated more biomass in the nutrient-rich floodplain soil. Soil type incluenced all growth parameters measured, but plant origin influenced only sme of these paramenters. Photosynthesis declined in all populations when root systems were flooded. This decline was delayed in sand-dune plants until after day 12, due perhaps to their stomatal conductance increasing initially and then declining. Response to drought was different also among the three populations. These findings indicate that Populus deltoides grows well across a wide range of soil conditions but exhibited ecological differentiation in the three contrasting habitats it usually occupies. THE MANIFESTATION OF DEHYDRATION AVOIDANCE IN WHEAT BREEDING GERMPLASM,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Div. of Field Crops.
A. Blum, G. Gozlan, and J. Mayer.
Crop Science, Vol 21, No 4, p 495-499, July/August, 1981. 3 Fig, 4 Tab, 11 Ref.

Descriptors: *Wheat, *Water stress, *Drought, Crop yield, Crop production, Irrigation effects, Stomata, Plant physiology.

The existence of and variability in dehydration avoidance was investigated within a random sample of advanced and well-adapted wheat. Selected genotypes were planted in each test and two replicate plots. Half of the plots were irrigated every 12 to 17 days, while stress blocks were not irrigated after September 24. Significant variation was found among the 19 genotypes tested in their midleaf water potentials during a stress period. Leaf water potential was correlated with the final number of grains per spike across genotypes of similar phenology in one test where drought stress developed during the spike development stage. Large variations in stomatal response were found, which indicated that dehydration avoidance in only a few of the genotypes may have resulted from stomatal sensitivity and closure at low stress levels. Most avoidant genotypes had relatively open stomata. Thus, a selection method for dehydration avoidance was investigated which, when combined with other available tests for drought resistance, may lead to the establishment of a logistic breeding program for improved yield and drought resistance in wheat. VEGETATIONAL ANALYSIS OF BIG RUN BOG, A NONGLACIATED SPHAGNUM BOG IN WEST VIRGINIA,
West Virginia Univ., Morgantown. Dept. of Biology.
R. K. Wieder, A. M. McCormick, and G. E. Lang.
Castanea, Vol 46, No 1, p 16-29, March, 1981. 2 Fig, 2 Tab, 15 Ref.

Descriptors: *Bogs, *Vegetation, *Plant populations, Population density, Spatial distribution, Shrubs, Mosses, Herbs, *West Virginia, *Big Run Bog.

Although there have been numerous studies of the vegetation of Sphagnum-dominated bogs and peatlands in glaciated areas and of the vegetation in extensive Sphagnum-dominated areas in nonglaciated regions, the numerous small sized bogs in nonglaciated regions have been largely ignored. The composition and distribution of the vegetation in a small, relatively undisturbed nonglaciated Sphagnum bog in West Virginia was investigated. Vegetation was sampled from late June through early September, 1977, in a series of nested quadrants in Big Run Bog in West Virginia. The following four community types were identified using a minimum variance cluster analysis of the data: Sphagnum-Eriophorum virginicum, Sphagnum-shrub, Polytrichum-shrub, and Polytrichum-Carex canescens. These four community types cover about 85 percent of the surface of the bog, with Sphagnum communities occurring in 122 of the 126 quadrants and Polytrichum occurring in 91 of the quadrants. Vascular herbaceous species cover about 50 percent of the surface of the bog. Upright shrubs are of relatively minor importance, and most of the shrub species are generally found near the edge of the bog. The six tree species were represented by only a few individuals, and dead trees and saplings were more numerous than live ones. Several species found in the Big Run Bog have generally boreal distributions but are found at or near the southern limit of their natural ranges in Sphagnum bogs in West Virginia. Marked changes in the composition of bog vegetation have been attributed to alterations of water table level. Frequent alterations of water table level resulting from intermittent beaver habitation may be responsible for the failure of the vegetation to segregate into distinct communities in this bog. The pattern of community distribution may be related to cation concentration of surface water, pH of surface water, and soil moisture, as well as to water table fluctuations. (Carroll-FRC)

PHOTOSYNTHETIC RECOVERY OF RESURRECTION SPIKEMOSSES FROM DIFFERENT HYDRATION REGIMES,
Vanderbilt Univ., Nashville, TN. Dept. of General Biology.
W. G. Eickmeier.
Oecologia, Vol 46, No 3, p 380-385, September, 1980. 5 Fig, 2 Tab, 29 Ref.

Descriptors: *Desert plants, *Photosynthesis, *Drought resistance, Xerophytes, Spikemosses, Mosses, Arid climates, Plant physiology, Humidity, Texas.

The patterns and mechanisms of photosynthetic activity recovery of two resurrection spikemosses were compared in the laboratory. The two plants, found in the southwest Texas desert, were Selaginella lepidophylla Hook. and Grev. (hot, arid, low elevation, xeric environment) and S. pilifera A. Br. (high elevation, mesic environment). Photosynthetic competence was achieved much more rapidly in S. lepidophylla than in S. pilifera. Although chloramphenicol, a chloroplast protein synthesis inhibitor, significantly inhibited resumption of C02 uptake in both species, inhibition was greater in S. pilifera. The level of conserved ribulose 1,5-bisphosphate carboxylase specific activity was significantly greater in S. lepidophylla. These results support the hypothesis that desiccation produces less damage to the photosynthetic system in plants from more xeric environments than in plants from mesic environments. (Cassar-FRC)

SEASONAL PATTERNS OF LEAF WATER RELATIONS IN FOUR CO-OCCURRING FOREST TREE SPECIES: PARAMETERS FROM PRESSURE-VOLUME CURVES,
Duke Univ., Durham, NC. Dept. of Botany.
S. W. Roberts, B. R. Strain, and K. R. Knoerr.
Oecologia, Vol 46, No 3, p 330-337, September, 1980. 8 Fig, 37 Ref.

Descriptors: Water potentials, *Drought, *Leaves, Soil-water-plant relationships, Trees, Osmotic pressure, Plant water potential, Forests, Seasonal variation, *Forests.

Leaf water relationships were studied in 4 forest tree species (Ilex opaca Ait., American holly; Cornus florida L., flowering dogwood; Acer rubrum, red maple; and Liriodendron tulipfera L., tulip poplar) during April-August 1977, a dry summer. Initial osmotic potentials (the value of the osmotic component at full turgidity) were highest at the start of the growing season and decreased as the summer progressed. Precipitation after a dry period caused an increase in initial osmotic potentials. All species but Acer maintained leaf turgor throughout the season; during the July drought Acer leaves lost some turgor at midday. Younger Ilex leaves had higher early season initial osmotic potentials than overwintering leaves from the same tree. In Liriodendron the osmotic potentials of the leaves appeared to be related to the resistance of these leaves to drought conditions. The osmotic water fraction (fraction of total leaf water available to affect osmotic potentials) was greatest in young tissue early in the season and declined throughout the season. The measured water relationships agreed with the relative positions of the species along a water-availability gradient in the order Cornus (wettest), Acer and Liriodendron (intermediate), and Ilex (driest). This suggests that these trees coexist in a drought situation because each species uses water maximally at different stages of the water availability cycle. (Cassar-FRC)

WATER RELATIONS, SOIL FERTILITY, AND PLANT NUTRIENT COMPOSITION OF A PYGMY OAK ECOSYSTEM,
Fisheries and Wildlife, Columbia, MO.
P. B. Reich, and T. M. Hinckley.
Ecology, Vol 61, No 2, p 400-416, 1980. 11 Fig, 3 Tab, 54 Ref.

Descriptors: *Water stress, *Nutrients, *Forests, *Ecosystems, Moisture availability, Growth, *Pygmy oaks, Trees, Soil properties, Seasonal variations, Temperature effects.

A study was conducted to describe the seasonal and spatial patterns of soil-plant moisture and nutrient relations for both a pygmy and a non-pygmy forest; to examine diurnal trends in plant water deficit, leaf conductance, and certain environmental variables; and to describe differences between seedling growth of acorns from pygmy and non-pygmy oaks. The study site was Buzzard's Roost, an unusual pygmy oak ecosystem in southwest Missouri. Pygmy forest soil was very acidic, with

low levels of calcium and magnesium and high levels of aluminum. Adjacent non-pygmy forests had higher pH, Ca and Mg, and lower Al levels. Diurnal and seasonal patterns of xylem pressure potential, leaf conductance, and soil moisture content illustrated the development of very severe tree water deficits at Buzzard's Roost. Predawn and midday xylem pressure potentials decline to as low as -3610 and -4200 kPa, respectively, accompanied by complete daytime stomatal closure. However, other factors indicated that water stress was not the major factor or causative agent in the stunting process. Very low nutrient levels in the soil may be partly responsible for the existence of the pygmy oak forest. The xeric site characteristics add another severe stress to this ecosystem. The adverse soil factors set up a 'feedback' system in which nutrient loss, acidification, and changing ion solubilities increase the soil impoverishment. (Baker-FRC)

WATER VAPOR CONDUCTANCE AND CO2 UPTAKE FOR LEAVES OF A C4 DESERT GRASS, HILARIA RIGIDA,
California Univ., Los Angeles. Lab. of Nuclear Medicine and Radiation Biology.
P. S. Nobel.
Ecology, Vol 61, No 2, p 252-268, 1980. 5 Fig, 32 Ref.

Descriptors: *Grasses, *Moisture availability, Soil moisture, *Soil-water-plant relationships, Photosynthesis, Transpiration, *Desert plants, Arid-zone hydrology, Hydrology, Arid zone, Arid lands, Arid climates, Carbon dioxide, Soil water, Hilaria rigida.

Transpiration and photosynthesis were examined over a 2 year period in the field and in laboratory conditions to help reconcile the prevalence of Hilaria rigida with potentially adverse ambient environmental factors. Availability of soil water appeared to be the major influence on seasonal stomatal activity of Hilaria rigida over the study period in the Colorado desert section of the Sonoran desert. Major stomatal opening occurred for 4.6 mo in the relatively cool winter-spring and for 1.7 mo in the late summer-early fall. The temperature optimum for carbon dioxide uptake was generally above daytime temperatures, particularly in the winter. When the daytime growth temperature was raised from 16 to 49 degrees C in laboratory experiments, the temperature optimum for CO2 uptake shifted from 29 to 43 degrees C. Besides the rather high temperature optimum for CO2 uptake, H. rigida displayed other typical C4 characteristics including Kranz anatomy, a low CO2 compensation point, and a lack of light saturation of CO2 uptake at full sunshine. Under optimal field conditions, the CO2 uptake rate can be higher than that reported for other species. The accompanying high after use efficiency may help explain the success of this hardy grass in both the Mojave and Sonoran deserts. (Baker-FRC)

RESPONSE OF FABABEAN YIELD, PROTEIN PRODUCTION AND WATER USE TO IRRIGATION,
Department of Agriculture, Lethbridge (Alberta). Research Station.
K. K. Krogman, R. C. McKenzie, and E. H. Hobbs.
Canadian Journal of Plant Science, Vol 60, No 1, p 91-96, January, 1980. 4 Fig, 2 Tab, 7 Ref.

Descriptors: *Moisture availability, *Crop yield, Moisture stress, Drought, Irrigation, Farming, *Fababeans, Seeds, Straw, Soil moisture, *Soil water-plant relationships, *Alberta, Canada.

The yield and quality responses of fababeans to variable soil moisture levels were investigated and the water requirements of this crop in southern Alberta were determined. Soil moisture was varied by time of stopping irrigation or by level of maintained moisture. Increased supplies of soil moisture increased the yields of seed, straw and crude protein. Evapotranspiration for the growing season averaged 544 mm, which is 16% greater than that of irrigated cereals. Efficiency of water use was about constant over the range of treatments, and yields were linearly correlated with evapotranspiration. Soil moisture must be maintained at least above 50% of the available range to achieve the full yield potential of fababeans. The potential yield of crude protein equals or exceeds that of other irrigated crops in southern Alberta. While limitations such as annual variations in length of growing season may prevent the attainment in all years of maximum yields as demonstrated in the tests conducted in this experiment, fababeans will produce high yields of seed and straw, representative of high production of vegetable protein, if soil moisture stress is not allowed to develop. DEBRIS FLOW DEPOSITS OF EARLY MIOCENE AGE, DEADMAN STREAM, MARLBOROUGH, NEW ZEALAND,
Canterbury Univ., Christchurch (New Zealand). Dept. of Geology.
D. W. Lewis, M. G. Laird, and R. D. Powell.
Sedimentary Geology, Vol 27, No 2, p 83-118, August, 1980. 16 Fig, 53 Ref.

Descriptors: *River basin development, *Geologic history, *Sediments, Flow, *Debris basins, Sandstones, Conglomerate rocks, Deadman stream, *New Zealand.

An analysis is presented on conformable succession of Early Miocene conglomerates and sandstones lying between massive marine mudstones in Deadman Stream, Marlborough, New Zealand. The coarse sediments were deposited by various subaqueous debris-flow mechanisms during an early pulse of tectonism that ultimately resulted in Plio-Pleistocene eversion of the Kaikoura Mountains. High-viscosity flows and slurry-creep flow meahanisms are reflected in sparse pebbly mudstones and rare sandy conglomerates. Low-viscosity flows are reflected by other deposits that have little mud matrix. The largest clasts in the deposits have a preferred planar orientation and a preferred long-axis orientation parallel to flow direction. Microfossil data from the mudstones indicate sedimentation in an environment of outer neritic to upper bathyl aspect. Most detritus is abraded, and deposits generally fill broad shallow channels. Channeling appeared to remain relatively fixed throughout the accumulation of hundreds of meters of superimposed, commonly amalgamated debris-flow deposits. The focus of deposition probably lay shoreward of any submarine canyon or fan. (Small-FRC)

HOLOCENE SEQUENCES ON AN EMBAYED HIGH-ENERGY COAST: AN EVOLUTIONARY MODEL,
Geological Survey of New South Wales, Sydney (Australia). Dept. of Mineral Resources and Development.
P. S. Roy, B. G. Thom, and L. D. Wright.
Sedimentary Geology, Vol 26, No 1/3, p 1-19, April, 1980. 7 Fig, 1 Tab, 35 Ref.

Descriptors: *Estuaries, *Sedimentation, *Erosion, Sands, Sediment transport, Tidal effects, Coasts, Model studies, Marine geology, *Australia.

An evolutionary model is proposed to account for the three types of Holocene embayment fill which can be applied to coastal erosion studies. Southeastern Australia has an embayed high-energy coast which shows varying degrees of infilling. The three types of embayment fill are open ocean, barrier estuary, and drowned river valley. In mid-Holocene times, the rapid accumulation of marine sand resulted in the formation of coastal sand barriers and of estuaries that progressively infilled with fluvial deposits. There is evidence that erosion dominated over accretion during the Late Holoene; sandy bays were deepened and many barriers retreated. Using the model, with extreme or prolonged wave erosion, barriers may be destroyed and estuarine deposits relocated to produce mixed fluvial/marine sediments. Also, when an estuary completely infills and river sand is supplied to the coast, similar polygenetic sediments are produced. Coastal erosion may be countered or reversed in cases such as these. Thus, the same mechanisms seem to add or remove sand, although the exact mechanism and its perhaps cyclic nature are not well understood. (Small-FRC)
W82-00695

MOVEMENT OF LOOSE, SANDY DETRITUS BY SHALLOW WATER FLOWS: AN EXPERIMENTAL STUDY,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Soils.
A. J. Moss, P. H. Walker, and J. Hutka.
Sedimentary Geology, Vol 25, No 1/2, p 43-66, January, 1980. 10 Fig, 30 Ref.

Descriptors: *Sediment transport, *Overland flow, *Sand, Sediments, Flow channels, River flow, Saltation, Suspended sediments, Suspended load, Bed load, Erosion rate, Erosion, *Detritus.

The interactions between flowing water and natural, loose, sandy detritus which contained small amounts of clay, silt, and pebbles were studied in flumes using small discharges over a large range of slopes. All flows strong enough to move the full size range of bed material were supercritical and channel systems always replaced the initial sheet flows after general sediment movement began. Behaviorally distinct suspended, saltation, and contact loads were found in flows as little as 1 millimeter deep. While suspended load was entrained wherever suitable particles were exposed, saltation load was always entrained to full transportational capacity in the upstream few centimeters of the bed, with later entrainment downstream balanced by deposition. Channel formation and geometry and the transportation of suspended and contact loads were largely controlled by the interaction between saltatory particles and the flow. Saltation changed from the movement of particles in individual trajectories to migration as ballistic dispersions with increased flow vigor. While saltatory grains moved in individual trajectories, transport rate increased rapidly with slope. However, the rheologic layer formed when the bed-load concentration reached about 25 percent by volume, after which transport rate increased less strongly with slope, closely following a stream-power law. Small rills were found to transport little sand when the slope was less than 0.01. However, transporting power increased significantly through the slope range 0.01 to 0.04 and became enormous by a slope of 0.3. Small overland discharges acquired considerable power to transport pebbles when flow was concentrated into channels. Processes in small channels were found to closely parallel those in rivers for the most part, but repetitive sedimentary structures contrasted sharply with those of deeper, subcritical flows. THE NATURE OF SELECTED PRAIRIE LAKE AND STREAM SEDIMENTS,
Saskatchewan Univ., Saskatoon. Dept. of Soil Science.
D. W. Oscarson, J. S. Rogers, P. M. Huang, and W. K. Liaw.
International Revue der Gesamten Hydrobiologie, Vol 66, No 1, p 95-107, 1981. 3 Fig, 5 Tab, 45 Ref.

Descriptors: *Sediments, *Chemical analysis, Clays, Lakes, Streams, Hydrobiology, Nutrients,

Pollutants, Organic matter, Minerals, *Saskatchewan, Canada.

The nature of sediments of selected lakes and streams of the upper Qu'Appelle River basin was examined. Sediment samples were taken from five lakes: Buffalo, Pound, Pasqua, Echo, Mission, and Katepwa, and the Qu'Appelle River, plus two of its tributaries. Principal crystalline clay minerals present in the colloidal fractions of the sediments were smectite, vermiculite, kaolinite, mica, quartz, and feldspar. The cation-exchange capacity of the sediments varied from 16.3 to 28.8 meq/100 g, and the pH ranged from slightly acid to slightly alkaline. The hydrous oxides of Al, Fe, Mn, and Si were present in significant quantities in both the colloidal and noncolloidal fractions of the sediments. These oxides may exert the dominant chemical control on nutrient movement and pollutant movement in aquatic environments. Calcium and magnesium carbonates comprise a significant fraction of the sediments. Most of the carbon in the sediments is in the organic form. The organic carbon content varied from 1.2 to 6.0%. Since crystalline clay minerals, poorly ordered sesquioxides, and organic matter play a vital role in the retention and cycling of nutrients and pollutants, knowledge of the nature and properties of sediments is essential in efforts to preserve and improve the quality of natural water systems. A. W. Peterson, and T. Blench.
Canadian Journal of Civil Engineering, Vol 7, No 1, p 93-104, 1980. 7 Fig, 1 Tab, 55 Ref.

Descriptors: *Rivers, *Channels, Bed load, Flumes, Irrigation canals, Canals, Computers, Gravel, Sand, Sedimentation, *Erosion, Reviews, Graphical methods, *Channeling, Channel forming, Sediment transport, Alluvial rivers.

The origin and potential of the four-dimensional charts produced from numerical data obtained from the equilibrium dimensions of sand rivers, gravel rivers, and laboratory flumes is presented. Problems in this field have included gross disagreements among sediment load predictions from various formulas, improper transfer of flow information to rivers and canals, and differences between sand and gravel rivers. These are caused by flumes working in a transition between phases, lack of communication between workers in the field, and inapplicability of pure deductive methods to fluid-solid mixtures. Examples of the subjects discussed are Indian sand-bed canal observations, information on gravel rivers, Cooper's (1970) world flume data analysis, and the Peterson Q-factor (volumetric water discharge) and S (slope). References chosen from the multitude written on this subject feature usable photos, graphs, and tables; freedom from specialized mathematics and speculation; and references to further useful information sources. EFFECT OF SLOPE LENGTH ON EROSION FROM LOW SLOPES,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
C. K. Mutchler, and J. D. Greer.
Transactions of the ASAE, Vol 23, No 4, p 866-869, 876, July/August, 1980. 2 Fig, 3 Tab, 6 Ref.

Descriptors: *Erosion rates, *Soil erosion, *Slope degradation, Mathematical studies, Slopes, Erosion, Runoff, Mathematical equations.

There is general acceptance of the premise that erosion increases with increasing slope length and that soil loss is proportional to slope length to some power, m. Investigations conducted over several years have resulted in the use of 0.5 as the slope length exponent for sloping farmland, with lower values being recommended for slopes of less than 4 percent. Since most of the intensively farmed flood plain soils in the United States are located on land comprised of nearly flat slopes, field studies were undertaken to determine the slope length exponents for these slopes. Simulated rainfall was applied to eight erosion plots ranging from 23 to 813 meters long on a slope of 0.2 percent. The study results support the slope length exponents recommended in Agriculture Handbook 537, although those exponents may be conservative for slopes of 1 percent. It is recommended that consideration be given to lowering the exponent to 0.15 for slopes less than 0.5 percent and to 0.2 for slopes between 0.5 and 1.0 percent. Ponding of water on part of the slope will cause the soil loss from the nearly flat slopes to be less than that predicted by the Universal Soil Loss Equation. (Carroll-FRC)

AERIAL PHOTOGRAPHY AS AN AID TO CROPLAND EROSION ANALYSIS,
Texas Christian Univ., Fort Worth. Dept. of Geology.
K. M. Morgan, D. R. Morris, G. B. Lee, R. W. Kiefer, and G. D. Bubenzer.
Transactions of the ASAE, Vol 23, No 4, p 907-909, 913, July/August, 1980. 2 Fig, 4 Tab, 10 Ref.

Descriptors: *Cropland, *Soil erosion, *Aerial photography, Photography, Remote sensing, Erosion rates, *Erosion control, Land management, Land use, Soil conservation, Data collections.

The development and implementation of effective soil conservation programs requires areawide erosion analysis. The Universal Soil Loss Equation is generally used to compute long-term soil losses from agricultural fields due to rill and interrill erosion for use in conservation planning. However, use of this equation is dependent on the collections of various data through field surveys. Remote sensing can provide total coverage of land use activities in watersheds and can supply accurate erosion information to agencies developing management plans for soil conservation. Color and color infrared photography at the scale of 1:60,000 were used to extract information about cropland management and conservation practices in Dane County, Wisconsin. Cropland management information determined by aerial photography included crop type, plowing, surface residue, and rotation. Information on erosion control practices covered contouring, strip cropping, and waterways. A detailed field survey of this agricultural watershed was also conducted by the Dane County Regional Plan Commission. The soil loss predictions developed on the basis of the results of the interpretations of the remote sensing air photographs were found to be in close agreement with the predictions made on the basis of the field survey results and computations made using the Universal Soil Loss Equation. SEDIMENT SIZES ERODED FROM CROP ROW SIDESLOPES,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
L. D. Meyer, W. C. Harmon, and L. L. McDowell.
Transactions of the ASAE, Vol 23, No 4, p 891-898, July/August, 1980. 5 Fig, 4 Tab, 16 Ref.

Descriptors: *Soil erosion, *Particle size, *Sediments, Soil properties, Physical properties, Erosion, *Cropland, Storm runoff, *Furrows.

The soil eroded from row sideslopes of land in rowcrop production and other interrill areas constitutes a significant proportion of the sediment from cultivated cropland during erosive rainstorms. The size distribution of these sediments is a major determinant of their transportability by runoff and their potential for subsequent deposition. Crop row sideslopes of ten soils, mostly silt loams, were tested under simulated rainstorms to determine the size distribution of the undispersed eroded sediment. These size distributions were compared with those of dispersed eroded sediment and of the original soil surface. The sizes of sediment eroded from crop row sideslopes varied considerably from soil to soil, both in magnitude and in distribution pattern. Aggregates comprised much of the sediment from cohesive soils. Sediments from fine soils were often coarser than those from soils with larger primary particle sizes due to the greater aggregation of the fine soils. Sediment sizes were not significantly affected by major changes in rainfall intensity, continued erosion, or the presence or absence of crop canopy. The undispersed eroded sediment was coarser than either the surface soil or the dispersed sediment for all soils, and much coarser for many soils. The size distribution of interrill sediment appears to be a fairly distinct characteristic of a given soil in a given condition. (Carroll-FRC)

Transactions of the ASAE, Vol 24, No 4, p 966-969, July/August, 1981. 3 Fig, 3 Tab, 6 Ref.

Descriptors: *Sedimentation, *Deltas, *Mississippi River, Rivers, Sediments, Sediment load, Sediment erosion, Erosion, Watersheds, Watershed management, Watershed protection, *Mississippi Delta.

Erosion and sediment yields from two adjacent watersheds in the Mississippi Delta over a 5 year period are reported. The watersheds are located on the G. L. McWilliams Farm near Clarksdale, Mississippi. One watershed had a silt loam soil and the other a silty clay soil. Practically all precipitation was in the form of rainfall. Both watersheds had been used for continuous cotton production for many years, including the 5 yr study period. The five annual amounts of rainfall were well distributed around their 5 yr average, which was within 2% of the long-term average amount. The 5-yr average monthly values differed greatly. Simple linear relationships were developed by grouping the sediment yield, runoff, and rainfall data by seasons. An equation for runoff was derived as a function of precipitation for data collected from November to June and another equation for data collected from July to October. Storm runoff was related to precipitation, and sediment yield was related to storm runoff during two seasons of the year. These equations were then combined to relate sediment yield to monthly rainfall for four separate crop and climatic periods. The equations derived should be suitable for predicting sediment yields and runoff from much of the 140,000 ha of graded flatland in the delta region. Care should be taken in using them outside of this climatic area. Erodibility of soils must be considered when predicting sediment yield. As these results represent sediment yield from watersheds with an essentially unrestricted outlet, they thus represent maximum values to be expected. (Baker-FRC)

MECHANICS OF MUDFLOW MOBILIZATION IN LOW-ANGLED CLAY SLOPES,
Michigan State Univ., East Lansing. Dept. of Civil and Sanitary Engineering.
L. E. Vallejo.

Engineering Geology, Vol 16, No 1/2, p 63-70, July, 1980. 2 Fig, 2 Tab, 17 Ref.

Descriptors: *Mudflows, *Clays, *Soil mechanics, Estimating equations, Erosion, Rocks, Slopes.

An analytical explanation of mudflow mobilization on flat surfaces is presented. Mudflows consisting of a mixture of hard clay fragments or rocks with mud can be considered a mass of concentrated grains that are dispersed in a flowing medium. The movement of the grain flow and the unit weight of the fluid medium can be quantified. The least slope angles of mudflow were calculated using the Bagnold theoretical method for field cases, and the calculated results compared well with field measurements. The Bagnold method is an alternative to the undrained loading and the excess pore water or artesian pressure effects which have been used to explain mudflow mobilization on some low angled slopes. The Bagnold method is successful because it is based on the assumption that a mixture of solids and fluid will flow instead of slide. It is an excellent tool to interpret mobilization of mudflows made up of hard clay fragments or pieces of rock in a soft clayey matrix such as mud. (Small-FRC)

CORRELATION OF MICROBIAL DEGRADATION RATES WITH CHEMICAL STRUCTURE,
Environmental Research Lab., Athens, GA.
N. L. Wolfe, D. F. Paris, W. C. Steen, and G. L. Baughman.
Environmental Science and Technology, Vol 14, No 9, p 1143-1144, 1980. 2 Fig, 22 Ref.

Descriptors: *Natural waters, *Microbial degradation, Biodegradation, *Organic compounds, Phenols, Kinetics, Hydrolysis, Sediments, Chemical reactions.

Relationships are established between structure and reactivity for the microbial degradation of selected organic compounds. Second-order microbial degradation rate constants were determined in natural water samples for six compounds and were found to correlate with the second-order alkaline hydrolysis rate constants. Also, second-order microbial degradation rate constants for four phthalate esters were obtained with organisms from sediment-water samples. These were shown to correlate with the second-order alkaline hydrolysis rate constants. Similar correlations are demonstrated for the rates of oxidation of substituted phenols by mixed microbial cultures isolated from soils and Hammett constants. It is important to note that the correlations demonstrated here offer some insight into a method of predicting microbial degradation rate constants in natural waters and perhaps soils as well. ACID PRECIPITATION: THE IMPORTANCE OF NITRIC ACID,
Virginia Univ., Charlottesville. Dept. of Environmental Sciences.
J. N. Galloway, and G. E. Likens.
Atmospheric Environment, Vol 15, No 6, p 1081-1085, 1981. 7 Fig, 26 Ref.

Descriptors: *Acid rain, *Nitric acid, *Sulfuric acid, Fossil fuels, Air pollution effects, Environmental effects, Precipitation.

Using the information on temporal trends of sulfate and nitrate ions accumulated from the long-term precipitation data collected at Hubbard Brook Experimental Forest, New Hampshire, temporal trends were determined in the maximum contributions of sulfuric acid and nitric acid to the acidity of the precipitation. Nitric acid in acid rain was introduced primarily by increased emissions of NOX from fossil fuel combustion. Its contribution to the acidity of precipitation is becoming increasingly significant. The maximum contribution of H2SO4 to the acidity of precipitation is 73% in summer and 59% in winter. For HNO3, it is 31% in summer and 61% in winter. This analysis indicated that the importance of H2SO4 has decreased by about 30% relative to HNO3 and HNO3 has increased by about 50% relative to H2SO4 for the years studied. These conclusions should be applicable to most of the eastern United States. (Small-FRC)

ACIDITY FLUCTUATIONS AT A BROADLAND SITE IN NORFOLK,
Ministry of Agriculture, Fisheries, and Food, Norwich (England). Coypu Research Lab.
L. M. Gosling, and S. J. Baker.
Journal of Applied Ecology, Vol 17, No 2, p 479-490, August, 1980. 5 Fig, 3 Tab, 20 Ref.

Descriptors: *Acidity, *Environmental effects, *Acidic soils, Water pollution, Chemical properties, Aquatic plants, Aquatic animals, Agriculture, Pyrite, Wetlands, Acidic water, Water, Sulfates, Oxidation, Sulfides, *Sulfuric acid, Tropical regions, *Soil chemistry.

Acid sulfate soils, which are soils containing a relatively high level of sulfides which on oxidation form sulfuric acid, pose serious problems for agriculture in tropical regions. The main difficulty experienced from such soils in Great Britain has been the clogging of field drains with ochre deposits. However, Calthrope Broad, a wetland site in Norfolk, experienced an abrupt change in acidity from near-neutrality to just above pH 3.0 in 1970. As a result, the entire fish population of the area died, as did freshwater mussels and most aquatic macrophytes. The first rise in acidity brought a dramatic invasion by the acidophilous alga Tribonema minus. The pH of free water returned to neutrality after a period of acute acidity, but similar fluctuations occurred in most years between 1971 and 1979. Dams maintain the perched water table in the area around the broad during the winter, but evaporation and seepage cause extreme drops in water levels during the summer. As a result, the agricultural soil, which was rich in pyrites, was subjected to alternate drying and saturation, causing oxidation of the pyrite and formation of sulfuric acid. Treatment by the addition of lime in 1978 maintained neutral water in the broad, even though the acidity of the water in adjacent ditches continued to fluctuate. While all plant groups present before 1970 reappeared, only one fish species has returned to the area. (Carroll-FRC)

CHEMISTRY OF LAKE WATER AND GROUNDWATER IN AREAS OF CONTRASTING GLACIAL DRIFTS IN EASTERN MINNESOTA,
Southern Illinois Univ. at Edwardsville. Dept. of Biological Sciences.
R. B. Brugam.
Hydrobiologia, Vol 80, No 1, p 47-62, April, 1981. 4 Fig, 7 Tab, 18 Ref.

Descriptors: *Lakes, *Chemical composition, Water analysis, Salts, Deicers, Calcium, Magnesium, Sulfates, Carbonates, Silicon dioxide, Groundwater, Ions, Roads, Water pollution sources, *Groundwater, Glacial drift, Glacial aquifers, Glacial lakes, *Minnesota.

During the winter of 1977-78 water samples were collected from 28 lakes in east-central Minnesota, 15 from Superior-lobe drift and 13 from Grantsburg-lobe drift. Groundwater samples were collected from wells near each lake. The major sources of ionic input into the study lakes are assumed to be groundwater and direct runoff from the watershed. Mann-Whitney U tests were used to determine if any statistical significance could be attached to differences between major-ion concentrations of lakes on tills of the Superior versus Grantsburg lobe. Concentrations of Ca(2+), Mg(2+), HCO3(-), SO4(-) were significantly higher in samples of groundwater from the Grantsburg lobe. No correlation was noted between groundwater concentrations of particular ions and lake-water concentrations of the same ions, implying that the sources of dissolved ions in lake water are shallow groundwater and soil leachates rather than the deeper groundwater sampled here. Na(+) and Cl(-) concentrations in some lakes appear to be strongly influenced by the use of de-icing salt on highways in winter rather than by differences in drift lithology. (Baker-FRC)

EFFECTS OF ION-PAIRING ON CALCULATIONS OF IONIC ACTIVITIES OF MAJOR IONS IN FRESHWATER,
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
C. E. Boyd.
Hydrobiologia, Vol 80, No 1, p 91-93, April, 1981. 2 Tab, 7 Ref.

Descriptors: *Natural waters, *Ionic interference, *Ions, Mineralization, Chemical reactions, Chemical composition, Chemical potential, Metals, Inorganic chemicals, Ion-pairing.

The objective of this study was to determine whether ion pairing had an appreciable effect on the calculation of ionic concentration, ionic strength, and ionic activities of major ions in natural waters. Measured ionic concentrations for 10 waters which represented a wide range in water chemistry were obtained from Livingstone. Ionic activities were first calculated by using the Debye-Huckel equation to calculate activity coefficients for all ions and multiplying the activity coefficients by the measured molar concentrations of the ions to give activities. Next, the iterative procedure of Adams was used to calculate ionic activities that were corrected for ion-pairing. Ion-pairing had no significant effect on ionic activities of Cl(-), Na(+), or K(+). The effect of ion-pairing on ionic activities of bicarbonate was slight. The influence of ion-pairing on ionic strength and ionic activities of Ca(2+), Mg(2+), and SO4(2-) increased with increasing ionic strength. The effect of ion pairing on the calculation of ionic strength was also substantial in the highly mineralized samples. These findings suggest that it is important in rigorous work to correct for ion-pairing in calculating ionic activities for all water samples except those that are not appreciably mineralized. A large percentage of the total iron, manganese, zinc, and copper in water exists as ion-pairs rather than as free ions. (Baker-FRC)

RELATIONSHIPS BETWEEN WATER CHEMISTRY AND RESPIRATION RATE IN SEVERAL POPULATIONS OF LYMNAEA PEREGRA MULLER (GASTROPODA:MOLLUSCA),
G. Dussart, and R. Kay.

Hydrobiologia, Vol 69, No 1/2, p 57-65, March, 1980. 4 Tab, 34 Ref.

Descriptors: *Chemical properties, *Mollusks, *Respiration, Oxygen, Hardness, Calcium, Potassium, Cations, Anions, Correlation analysis, Water quality.

In this investigation of the effects of water chemistry on L. peregra, the most important components producing such effects were determined. Specimens were obtained in North West England; respiration rates were studied in the laboratory, and the effects of water chemistry on weight-specific oxygen consumption were noted. Some relationship was found between water chemistry and wet-dry weight ratios, between oxygen consumption and live-wet weight, and between oxygen cosumption and shell-free dry weight. There were interpopulation differences in respiration rates between snails from different sites within the same water hardness classification. Calcium and potassium concentrations appeared to significantly affect respiration rates when tested in waters of varying cations but constant anion concentrations. Cations included calcium, sodium, magnesium, and potassium. The anion used was bicarbonate. No significant differences were found in respiration rates of populations of snails taken from the same site but in different years. (Small-FRC)

BIOGEOCHEMISTRY OF THOREAU'S BOG, CONCORD, MASSACHUSETTS,
Massachusetts Inst. of Tech., Cambridge. Dept. of Civil Engineering.
H. F. Hemond.
Ecological Monographs, Vol 50, No 4, p 507-526, December, 1980. 14 Fig, 6 Tab, 42 Ref.

Descriptors: *Bogs, *Hydrogen ion concentration, *Acidity, Swamps, Chemical properties, Acid rain, Peat soils, Ions, Geologic history, *Biochemistry, *Thoreu's Bog, Massachusetts.

The pH control mechanism of the bog system of Thoreau's Bog or Gowings Swamp is presented in terms of the interaction of mineral acidity and weak acids. This bog is a floating-mat Sphagnum bog developed in a glacial kettle hole. The bog is ombrotrophic, with an annual water input of 1.45 m and an annual runoff of 0.24 m. Metal inputs are: 88 mg/sq m/yr for K, 132 mg/sq m/yr for Mg, and 54 mg/sq m/yr for Pb. The distribution of K and Mg is vertical in accordance with the inhomogeneous ion exchange chemistry of peat, while lead is distributed in accordance with historical trends in atmospheric lead fallout. Net peat accumulation rate was 180 g/sq m/yr, and annual storage rates were 36 mg/sq m/yr for K, 54 mg/sq m/yr for Mg, and 46 mg/sq m/yr for Pb. Organic acids at concentrations of 10 to the minus 3rd power eg/liter maintain bog acidity at pH 3.8. The contribution of acid rain is offset by alkalinity increases of the same magnitude resulting from sulfate reduction and nitrate uptake. (Small-FRC)

ANALYSIS OF PRECIPITATION CHEMISTRY AT A CENTRAL PENNSYLVANIA SITE,
Pennsylvania State Univ., University Park. Dept. of Meteorology.
V. C. Bowersox, and R. G. De Pena.
Journal of Geophysical Research, Vol 85, No C10, p 5614-5620, October, 1980. 10 Fig, 2 Tab, 11 Ref.

Descriptors: *Chemistry of precipitation, *Sulfates, *Acid rain, Acidity, Nitrates, Ammonia, Hydronium ion, Snow, Storms, Seasonal variation, Pennsylvania, Rain, Precipitation.

Data collected at the multistate atmospheric power production pollution study (MAPPPS) precipitation chemistry network were analyzed in detail. Precipitation was sampled on a storm-by-storm basis at a rural central Pennsylvania site during the period January 1, 1977, to December 31, 1978. Samples were analyzed for sulfate, nitrate, ammonium, and hydronium ion concentrations. Sulfate concentration varied seasonally, with high values in summer and low values in winter. Sulfate is of interest as the major determinant of precipitation acidity, particularly in rain. The principal contributor to H3O was sulfuric acid, but the acidity of snow was determined principally by NO3. The NH4 in precipitation can be explained by assuming equilibrium between cloud water and gaseous ammonia in air. There was a good stoichiometric balance of the four major inorganic ions. Knowledge of the nature of acid-determining components in rain can be used to help establish strategies to control the quality of precipitation. (Small-FRC)

MASS-TRANSPORT LIMITATION TO THE RATE OF REACTION OF GASES IN LIQUID DROPLETS: APPLICATION TO OXIDATION OF SO2 IN AQUEOUS SOLUTIONS,
Brookhaven National Lab., Upton, NY.
S. E. Schwartz, and J. E. Freiberg.
Atmospheric Environment, Vol 15, No 7, p 1129-1144, 1981. 14 Fig, 2 Tab, 29 Ref.

Descriptors: *Oxidation, *Sulfur compounds, Sulfur dioxide, Water pollution sources, Clouds, Fog, Chemical reactions, Mass transfer.

The role of mass transport in the oxidation of sulfur dioxide to sulfate in aqueous droplets is considered. As in any gas-liquid reaction, competition between mass transport and reaction is involved. Characteristic times associated with the several steps in the overall process have been identified, and expressions presented whereby these characteristic times may be evaluated for reactions in spherical drops. By comparing these characteristic times it may be determined whether a measured rate of reaction is equal to the intrinsic reaction rate or is limited by mass transport in the gas phase, at the air-water interface, or in the aqueous phase. Criteria are suggested that must be fulfilled for spatial and temporal uniformity to be achieved under experimental conditions or in the ambient atmosphere. Three steady-state criteria must be satisfied in order for a steady state to be achieved. After a steady state is reached, the concentration profiles may or may not be established at the surface, depending on the relative magnitudes of the several characteristic times. A theoretical model is presented wherein the extent of decrease in reaction rate may be calculated for each of the three mass-transport limiting processes, for a reaction that is first order in the concentration of the dissolved reagent species, and for mass transport in each of the two phases occurring by molecular diffusion. This theoretical framework has been applied to an examination of laboratory studies of sulfur dioxide oxidation in suspended droplets and to consideration of mass transport limitation to the rate of oxidation of sulfur dioxide in clouds and fogs. (Baker-FRC)

CHEMICAL MASS-WASTING OF THE NORTHERN YUCATAN PENINSULA BY GROUNDWATER DISSOLUTION,
Geological Survey, Reston, VA.
B. B. Hanshaw, and W. Back.
Geology, Vol 8, No 5, p 222-224, May, 1980. 2 Fig, 9 Ref.

Descriptors: *Erosion rates, Saline-freshwater interfaces, *Dissolution, Calcite, *Yucatan Peninsula, *Chemical degradation, Grounwater recharge, *Carbonate rocks, Limestone, Recharge, Solubility.

The northern part of the Yucatan Peninsula is the site of chemical erosion in its Tertiary carbonate rocks, predominantly limestone. For the 65,500 sq km study area, the mean annual discharge (equivalent to recharge) is 9800 million cu meters or 8.6 million cu meters for each 1 km of the 1100 km coastline. The area is flat and lowlying, with no stream channels. Rainfall averages 1000 mm per year. Soil cover is thin, infiltration is rapid, and transmissivity of the limestone is very high. Inland, the recharging fresh water becomes saturated with calcite, dissolving about 37.5 metric tons of calcite per sq km per year as it flows toward the coast. At the coast, the saline water also becomes saturated with calcite. When these two saturated waters of different salinities mix in the dispersion (or active mixing) zone the resulting solution is capable of dissolving as much as 1.2 nmol per liter additional calcite (or an additional 8.6 million mol per km coastline per year). The discharge near Xel Ha is about nine times greater than the average for the coastline. Calculations indicate that the lagoon in this area could be chemically incised within 3000 years. The zone of dispersion, about 3 m thick and extending 1 km inland, could completely dissolve in about 8700 years. (Cassar-FRC)

PHOSPHORUS, NIROGEN, AND ORGANIC CARBON FLUX IN A HEADWATER STREAM,
Georgia Univ., Athens. Dept. of Zoology.
J. L. Meyer, G. E. Likens, and J. Sloane.
Archiv fur Hydrobiologie, Vol 91, No 1, p 28-44, March, 1981. 5 Tab, 46 Ref.

Descriptors: *Streams, *Nutrients, *Chemical properties, Phosphorus, Nitrogen, Carbon, *Ecosystems, Seasonal variation, Organic carbon, Nitrogen compounds, Particulate matter, Dissolved solids, Gases, *Solute transport, Chemical reactions, Environmental effects.

Physical, chemical, and biological processes which transform nutrients entering a stream ecosystem affect the rate of transport of the element as well as its availability to the biological community. The processes responsible for these conversions in a particular stream will vary in form, rate, and relative importance for different elements. The processing of phosphorus, nitrogen, and organic carbon in Bear Brook, a forest stream in New Hampshire, were examined by constructing mass balances for each element over a one-year period. Annual inputs of nitrogen exceeded exports by 8 percent, while exports of phosphorus exceeded inputs by 12 percent. An earlier study assumed that the organic carbon budget was balanced. The stream exported 69 percent of the coarse particulate organic carbon inputs, 78 percent of coarse particulate organic nitrogen inputs, and 73 percent of coarse particulate organic phosphorus inputs in the form of fine particulates (between 0.45 micrometers and 1 millimeter), dissolved solids (less than 0.45 micrometers), or gases. Organic carbon was exported primarily in the gaseous or dissolved fraction, phosphorus was exported mostly as fine particulates, and nitrogen was transformed primarily to dissolved matter. Fluvial inputs had lower carbon to nitrogen and carbon to phosphorus ratios and a higher nitrogen to phosphorus ratio than did fluvial exports. There was a lower nitrogen to phosphorus atomic ratio in fluvial exports during the growing season than during the rest of the year. The discharge relationships observed for these elements suggest that annual changes in streamflow have different effects on the export/input ratio for each element, with organic carbon budgets showing the least variation, followed by nitrogen. The phosphorus budget appears to be the most sensitive to changes in the annual discharge. (Carroll-FRC)

NUTRIENT BUDGET STUDIES FOR FORESTS ALONG AN ELEVATIONAL GRADIENT IN NEW MEXICO,
New Mexico Univ., Albuquerque. Dept. of Biology.
J. R. Gosz.
Ecology, Vol 61, No 3, p 515-521, 1980. 1 Fig, 2 Tab, 24 Ref.

Descriptors: *Nutrients, *Ecosystems, Forests, Cycling nutrients, *Watersheds, Soils, Hydrology, Calcium, Magnesium, Potassium, Sodium, *New Mexico, Nutrient budget.

This paper reports studies of element inputs in bulk precipitation and outputs in stream water for a number of watersheds in New Mexico. These watersheds are located in the Tesuque Watershed Study area in the Sangre de Cristo Mountains. A number of vegetational zones occur in this area due to the influence of elevation on temperature and moisture gradients. The net organic matter increment of one of the watersheds has been estimated to be negative. The patterns in the output

and net change of calcium, magnesium, potassium and sodium among watersheds are related to soil chemistry and stream discharge rates. These factors may not be related to soil chemistry and stream discharge rates. These factors may not be related to the net organic matter increment of the ecosystem. Actual atmospheric inputs of these elements to some of the ecosystems may be an order of magnitude greater than those measured in bulk precipitation. Nitrogen outputs in stream water are strongly regulated by all of the watershed ecosystems, including the one which appears to have a negative net oganic increment. Low losses of nitrogen in stream water, however, do not mean that a system will minimize other types of N losses such as denitrification. Nutrient budgets generated from bulk precipitation and stream water discharge in the Southwest cannot prove or disprove hypotheses about nutrient regulation by net organic matter increment. Additional inputs and outputs must be quantified before a valid test can be made of the hypothesis. (Baker-FRC)

Descriptors: *Estuarine environment, *Oil pollution, *Sediments, Suspended sediments, Suspended solids, Ecosystems, Ecology, Hydrocarbons, Fate of pollutants.

The interaction of oil hydrocarbons with estuarine suspended particulate matter and sediments is considered. No. 2 fuel oil was added as a dispersion in semiweekly doses to three controlled estuarine ecosystems. Samples of suspended particulate matter and sediments were analyzed by gas chromatography for saturated and aromatic hydrocarbons. Fractionation of the oil in the water column by adsorption to particulate matter resulted in the sedimentation of about 50% of the insoluble, saturated hydrocarbons, but less than 20% of the more soluble, aromatic hydrocarbons. The oil-derived hydrocarbons were slowly mixed down through the bioturbation zone. Biodegradation and other processes effected the removal of most of the hydrocarbons soon after the additions ended, but a residue of 10-20% in the form of branched alkanes, cycloalkanes, and aromatics in an unresolved complex mixture persisted more than 1 year later. Descriptors: *Model studies, *Fjords, *Flow characteristics, *Flow friction, *Tidal effects, Mathematical models, Inlets, Flow characteristics, Stratification, Mixing, Tidal hydraulics, Froude number, *Saline-freshwater interfaces, *Knight Inlet, British Columbia.

A theoretic model describing steady flow in a strongly stratified fjord inlet was compared to the observed flow behavior of Knight Inlet, British Columbia. Some aspects of the model gave closer agreement with reality than others. The model was useful in assessing the limit of small interfacial friction coefficients. Interfacial friction was previously thought to dominate the flow. Inlets of this type possess circulations which usually adjust to maintain the interfacial Froude number at unity near the mouth. However, evidence is presented to show that Knight Inlet does not conform to this pattern. The mean circulation in this inlet was found to be driven by tidal interactions with little contribution from the wind. (Geiger-FRC)

The effects of environmental factors on seasonal changes in microbial populations were studied in the Tvarminne area, off the southern coast of Finland. Samples were collected at surface levels over 1 to 2 week intervals in 1976-78. Fourteen microbiological and 10 environmental parameters were determined. Stepwise multiple regression analysis was used to explain seasonal variation in the microbiological parameters. Separate analyses were made of the data from the open-water and ice-covered periods. In analyses of data from both periods, the environmental factors included accounted for a significant proportion of the variation in the parameters for community respiration (90%) and bacterial spores (80%), and a smaller proportion (60-65%) of the variation in total counts of bacteria and plate counts of psychrophiles and yeasts. Lower values (40-55%) were obtained for the variation in the other microbiological parameters. The environmental factors with maximal contributions were organic matter, water temperature, chlorophyll, and salinity, but rainfall and winds also explained part of the variation in some microbiological parameters. In winter studies the results differed from all other seasons, the variation being controlled by parameters indicative of freshwater outflows, including humic matter, salinity, water temperature, and rainfall. SPATIAL DISTRIBUTIONS OF POLLEN IN SURFACE SEDIMENTS OF THE POTOMAC ESTUARY,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
G. S. Brush, and R. S. DeFries.
Limnology and Oceanography, Vol 26, No 2, p 295-309, March, 1981. 5 Fig, 6 Tab, 23 Ref.

Descriptors: *Pollen, Sediment transport, Land use, *Estuaries, *Sediments, Tracers, *Potomac River, Trees, Deposition, Tidal effects, *Spatial distribution.

Tree pollen in surface sediments of the Potomac Estuary was proportionally representative of trees growing in the area for many of the species (oak, pine, birch, hickory, elm, ash, and hazelnut-ironwood). No pollen from the tulip poplar, a major tree, was found in sediments, probably because its flowers do not release pollen to the air. Sweet gum, red maple, beech, holly, and black gum were underrepresented by the pollen, and a few minor species were overrepresented. Pollens from trees restricted to the upper watershed 60 km upstream of the tidal limit were not present in downstream estuarine deposits. Comparisons of the variability in the pollen data and in the corresponding tree data from the adjacent watershed led to conclusions that pollen grains are differentially dispersed before being deposited and are not transported great distances. These studies imply a possible use of pollen as tracer particles to determine the effects of land use on one part of a watershed on various parts of the estuary. (Cassar-FRC)

GENERAL MORPHOLOGY AND SEDIMENT PATTERNS IN TIDAL INLETS,
South Carolina Univ., Columbia. Dept. of Geology.
M. O. Hayes.
Sedimentary Geology, Vol 26, No 1/3, p 139-156, April, 1980. 16 Fig, 1 Tab, 29 Ref.

Descriptors: *Inlets, *Sedimentology, *Tidal effects, Estuaries, Sediment transport, Morphology, Deltas, Channel morphology, Tides, Sandbars.

Inlet-affiliated sedimentary barrier island units usually include an ebb-tide delta, a flood-tide delta, and inlet-fill sequences created by inlet migration and recurved spit growth. Ebb-tide deltas include a main ebb channel flanked by linear bars on either side and a terminal lobe at the seaward end. The channel is bordered by a platform of sand with swash bars. Here the sand is coarse and contains polymodal cross-bedding with a slight ebb dominance. Flood-tidal deltas include a flood ramp and bifurcating flood channels on the seaward side and ebb shields, ebb splits, and spillover lobes on the landward side. A stratigraphic sequence of a typical flood tidal delta would be bidirectional, large-scale crossbedded sand at the base, predominantly large-scale crossbedded sand in the middle, and finer-grained tidal flat and marsh sediment at the top. Inlets migrate depending upon such variables as rate of longshore sediment transport and depth of inlet. Inlet-fill contains coarse, bidirectional crossbedded sediments at the base, polydirectional crossbedded sands in the middle, and finer-grained aeolian sands at the top. (Small-FRC)

EFFECT OF PH AND REDOX POTENTIAL ON CONCENTRATION OF DISSOLVED NUTRIENTS IN AN ESTUARINE SEDIMENT,
Louisiana State Univ., Baton Rouge. Lab. for Wetland Soils and Sediments.
R. D. De Laune, C. N. Reddy, and W. H. Patrick, Jr.
Journal of Environmental Quality, Vol 10, No 3, p 276-279, July/September, 1981. 2 Fig, 2 Tab, 17 Ref.

Descriptors: *Nutrients, *Marine sediments, *Estuaries *Hydrogen ion concentration, *Oxidation-reduction potential, Phosphorus, Carbon, Ammonia, Iron, Manganese, Sediments, Dissolved solids, Gulf of Mexico.

Although both sediment redox potential and sediment pH have been shown to affect the exchange

of nutrients at the sediment-water interface, most studies dealing with these effects have been theoretical in nature. This study investigated the combined effect of pH and redox potential on the concentrations of dissolved organic carbon, phosphorus, ammonia, iron, and manganese in an estuarine sediment in the Gulf of Mexico. Sediment suspensions were maintained under conditions of controlled pH (5.0, 6.5, and 8.0) and controlled redox potentials (-200, 0, 250, and 500 mV). Nutrient concentrations were found to be strongly influenced by changes in sediment pH and in redox potentials. Dissolved organic carbon increased from 42 micrograms per milliliter at pH 5.0 and 500 mV to 93 micrograms per milliliter at pH 8.0 and -200 mV. Decreasing sediment redox potential and pH resulted in increases in the concentrations of soluble phosphorus, ammonia, iron, and manganese. Phosphorus concentrations ranged from 0.002 micrograms per milliliter at pH 8.0 and 500 mV to 0.215 micrograms per milliliter at pH 5.0 and -200 mV. The concentrations of iron and manganese ranged from less than 0.1 micrograms per milliliter at pH 8.0 and 500 mV to 101 and 13 micrograms per milliliter, respectively, at pH 5.0 and -200 mV. The influence of sediment redox potential and pH on concentration gradients between interstitial and overlying water can result in fluxes of dissolved constituents to and from the sediment. The results of this study demonstrate the need to consider the influence of variables such as sediment redox potential and pH in models of the diffusion of chemical and biochemical reactive elements across the sediment-water interface. THE ASSAY OF ADENOSINE 5'TRIPHOSPHATE EXTRACTED FROM SALT-MARSH MICROBIOTA,
South Carolina Univ., Columbia. Dept. of Biology.
L. H. Stevenson, C. A. Wilson, and T. H. Chrzanowski.
Canadian Journal of Microbiology, Vol. 27, No. 6, p 633-635, 1981. 1 Fig, 1 Tab, 9 Ref.

Descriptors: *Adenosine triphosphate, *Salt marshes, Chemical analysis, Enzymes, Bacteria, *Estuaries, Microorganisms, Marshes, Coastal waters, Tidal marshes, Aquatic life.

Data were collected to test the theory that the method employed to assay the adenosine 5'-triphosphate extracted from aquatic microbiota influences the temporal pattern of ATP density in the water of a salt-marsh creek. Water was collected from within the North Inlet Marsh, near Georgetown, SC. The sampling location monitored the major exchange point between the marsh and the Atlantic Ocean. Water was collected from 0.2 meters below the surface at 1.5 hr intervals comprising several tide cycles during February of 1979. The effect of the secondary emission pattern on the quantification of ATP was studied through 52 samples taken during the two expeditions. Assays using the integration approach produced values that were from 1.13 to 8.22 times higher than values determined by peak height analysis of the unfiltered samples and from 1.18 to 16.39 time higher in water that had been prefiltered by passage through a 1.0 micron filter. The latter samples contained bacteria as the only viable microbiota. ATP concentration values determined by integration averaged 3.6 times greater than values determined by peak height in the unfiltered samples and 4.8 times greater in the 1.0 micron filtered samples. Extracts prepared from biota in high-tide or oceanic waters did not have as great an enhanced secondary emission pattern as did extracts of samples collected at low tide. It would appear that bacteria were responsible for most of the enhanced secondary emissions observed in samples collected at or near low tide. Thus the method used to assay ATP extracted from environmental samples markedly influences the data recovered. (Baker-FRC)

DIEBACK OF SALT-WATER CORDGRASS (SPARTINA ALTERNIFLORA LOISEL.) IN THE LOWER CAPE FEAR ESTUARY OF NORTH CAROLINA: AN EXPERIMENTAL APPROACH TO RE-ESTABLISHMENT,
North Carolina State Univ. at Raleigh. Dept. of Botany.
R. A. Linthurst, and E. D. Seneca.
Environmental Conservation, Vol 7, No 1, p 59-66, Spring, 1980. 6 Fig, 5 Tab, 39 Ref.

Descriptors: *Spartina, *Marsh plants, *Plant growth, Vegetation, *Estuaries, Ecosystems, Marshes, Wetlands, Plant communities, Salt marshes, *Cape Fear Estuary, North Carolina.

Panne dieback of Spartina alterniflora in the Lower Cape Fear Estuary of North Carolina prompted a study, starting in 1975, of this phenomenon and the recolonization potential in the affected marshes. By September 1978 all three sites investigated (2 above and 1 below mean high water) had naturally recolonized by seeding, mainly S. alterniflora. Volunteers at the lower site were largely S. alterniflora; at the 2 higher sites, Salicornia europaea, Distichlis spicata, Scirpus robustus, and Spartina patens were also found. Experimental plots within each dieback site were regenerated most rapidly by volunteer plants transplanted from areas similar to the dieback sites and/or plants with large rhizome systems. It was concluded that this dieback was a short-term phenomenon and that natural recolonization, not man's revegetation attempts, was the major factor in reestablishment of the plants. (Cassar-FRC)

EFFECTS OF TEMPERATURE, PH, SALINITY, AND INORGANIC NITROGEN ON THE RATE OF AMMONIUM OXIDATION BY NITRIFIERS ISOLATED FROM WETLAND ENVIRONMENTS,
University of West Florida, Pensacola. Dept. of Biology.
R. D. Jones, and M. A. Hood.
Microbial Ecology, Vol 6, No 4, p 339-347, 1980. 3 Fig, 24 Ref.

Descriptors: *Nitrification, *Oxidation, *Ammonium, *Estuarine environment, Nitrogen, *Wetlands, Temperature, Salinity, Hydrogen ion concentration, Bacteria, Marshes, Sodium, Potassium, Nitrate, Nitrite, Nitrogen cycle, Cycling nutrients.

The transformation of nitrogen and its recycling are extremely important to the productivity of aquatic ecosystems. Although factors affecting ammonium oxidation in agricultural soils and sewage have been investigated, information on factors affecting nitrification in wetland environments is lacking. Ammonium-oxidizing bacteria were examined in a freshwater marsh and in an estuarine bay over a 2-year period. Two predominant species of Nitrosomonas were consistently isolated, one from each environment. A closed culture, high cell density assay was used to determine the effects of temperature, pH, salinity, sodium, potassium, nitrite, nitrate, and ammonium concentrations on nitrification. Maximum oxidation of ammonium by the freshwater isolate occurred at 35 degrees C, pH 8.5, salinities of 0.3 to 0.5 percent sodium and potassium, and ammonium concentrations exceeding 0.5 grams per liter. The estuarine isolate exhibited maximum activity at 40 degrees C, pH 8.0, salinities of 0.5 to 1.0 percent sodium and potassium, and 0.2 grams of ammonium per liter. The sodium requirement of the estuarine isolate could be partially substituted by potassium, suggesting that the organism is a true estuarine bacterium. Salinities below 0.5 percent may severely reduce oxidation of ammonium by the bacterium in the estuarine environment. While nitrate had no significant effect on either isolate, certain combinations of ammonium nitrite were inhibitory, especially to the estuarine species. The data indicate that oxidation of ammonium by isolates from wetlands is influenced by pH and temperature and that estuarine nitrifiers may be more sensitive to and more extensively affected by salinity, ammonium concentrations, and nitrite than are isolates from fresh waters. SEASONAL INFLUX AND DECOMPOSITION OF AUTOCHTHONOUS MACROPHYTE LITTER IN A NORTH TEMPERATE ESTUARY,
New Hampshire Univ., Durham. Jackson Estuarine Lab.
M. N. Josselyn, and A. C. Mathieson.
Hydrobiologia, Vol 71, No 3, p 197-208, June, 1980. 8 Fig, 4 Tab, 38 Ref.

Descriptors: *Detritus, *Aquatic plants, *Decomposition, Estuaries, Spartina, Zostera, Ascophyllum, Fucus, Nutrients, Great Bay, New Hampshire, Maine, Coastal waters, Salt marshes, Marshes, Algae, Nitrogen, Phosphorus, Seasonal variation.

The seasonal contribution and detrital processing of autochthonous plant litter in the Great Bay Estuary system of New Hampshire and Maine was studied for 18 months. Monthly strand line collections at two inner estuarine sites and one open coast site provided information on the seasonal influx of litter derived from each species, the halophytes, Spartina alterniflora Loisel and Zostera marina L., and the seaweeds, Ascophyllum nodosum L. Le Jolis and Fucus vesiculosus L. v. spiralis Farlow. S. alterniflora ditrital inputs were maximal in spring; Z. marina inputs, in summer. Seaweed litter was 35-85% of the total strand lien throughout the year. In the estuary the seaweeds contributed 1 to 3 times as much detrital matter as did the vascular plants, on the open coast 50 times as much. Seaweeds decomposed 3-10 times faster than vascular plant litter (which contains more cellulose) under similar environmental conditions. Decomposition was faster under submerged conditions. Nutrient depletion occurred in litter within the strand line. N and P enrichment from microbial activity and rapid leaching of carbonaceous substrates were observed under submerged conditions. MICROBIOLOGICAL STUDIES OF A 'VIRGIN' SALT-FRESH WATER TRANSECT AT NORTH POINT, JAMES BAY, CANADA. I: BACTERIOLOGICAL ASPECTS,
Canada Centre for Inland Waters, Burlington (Ontario).
B. J. Dutka, and K. K. Kwan.
Hydrobiologia, Vol 72, No 3, p 273-280, July 2, 1980. 8 Fig, 2 Tab, 12 Ref.

Descriptors: *Baseline studies, *Bacteria, Wetlands, Salt marshes, Marshes, *James Bay, *Canada, Water analysis, *Microbiological studies, Sulfur bacteria, Eutrophication, Biomass, Saline-freshwater interfaces, Biodegradation, Sediments.

Bacterial populations were studied in water and sediment samples along a salt-fresh water shoreline transect at North Point, James Bay in northern Canada. Microbiological analysis showed that there was a very large microbial population, the greatest density occuring at the seawater stations. The few fecal indicator bacteria were a result of the animal population, not man's presence. Organic sulfur-reducing bacterial increased from 10,000 per 100 ml at the seawater stations to 100,000 per 100 ml at the brackish-fresh water interface. Sulfur-oxidizing bacteria varied from 10 to 100 per 100 ml, with highest densities in the marshland stations. Population patterns of ammonifying and denitrifying bacteria were quite similar to each other, with

ammonifiers 10 times more plentiful than denitrifiers. At the sea stations ammonifiers were high and denitrifiers low, with peaks of both in the salt marsh area. The high bacterial and heterotroph populations in the seawater stations indicate very eutrophic water. The potential biodedradation capacity of these waters is much greater than was formerly expected. (Cassar-FRC)

Descriptors: *Fungi, *Baseline studies, Wetlands, Marshes, *James Bay, *Canada, Water analysis, Sediments, *Microbiological studies, Saline-freshwater interfaces.

Baseline values for fungi were determined along a salt-fresh water transect in the unimpacted North Point, James Bay, Canada, area. Fungi levels in water samples increased linearly from 28-70 CFU per 100 ml at the salt water end of the transect to 13,000-16,000 CFU per 100 ml at the fresh water end. In sediments the highest fungal densities were found inland at sites with rich, black organic sediments. Lowest fungi levels were found in sediments composed of clay and shingle fragments. SUPERSEPARATION: SORET EFFECT REVERSED,
Scripps Institution of Oceanography, La Jolla, CA. Physiological Research Lab.
H. T. Hammel, and J. E. Maggert.
Separation Science and Technology, Vol 15, No 2, p 81-87, 1980. 1 Fig, 1 Tab, 2 Ref.

Descriptors: *Desalination apparatus, *Separation techniques, Soret effect, Osmotic pressure, Salt balance, Drinking water.

The Soret effect is attributed primarily to the fact that osmotic pressure is uniform across a solution when one side is heated and the other is cooled. When Whatman no. 40 filter paper was interspersed throughout an aqueous solution to minimize disturbance of the Soret effect caused by convection, the Soret effect was reversed. The concentration increased exponentially from nearly pure water at the cooled surface to many times the initial concentration at the heated surface. If the solution and filter paper were degassed, then the Soret effect was normal. It was concluded that microbubbles of air were entrained in the solution by the filter paper so that water vaporized on the warmer side of each bubble and condensed on the cooler side, thereby concentrating the solution near its heated surface and diluting it near its cooled surface. Continuous separation of seawater into potable water from the cooled surface was not possible in the described cell as the entrapped air in the filter paper was slowly absorbed by the condensate and removed from the cell. Continuous production of potable water was achieved, however, from a film of seawater flowing down a heated surface and supported a fraction of a millimeter from a cooled surface on which the vapor condensed and drained into a collecting trough below. 3B. Water Yield Improvement

CONTROL OF WATER WEEDS BY GRASS CARP IN TWO SMALL LAKES,
Marine Dept., Rotorua (New Zealand). Fisheries Research Div.
C. P. Mitchell.
New Zealand Journal of Marine and Freshwater Research, Vol 14, No 4, p 381-390, 1980. 4 Fig, 19 Ref.

Descriptors: *Weed control, *Aquatic plants, *Carp, *Fish, Lakes, Plant growth, Waihi Beach Reservoir, Parkinsons Lake, *New Zealand, Lake restoration.

Chinese grass carp (Ctenopharyngodon idella Val.), averaging 2 kg in weight, were incrementally stocked over a 3 year period in 2 small New Zealand lakes, Waihi Beach Reservoir, a water supply impoundment, and Parkinsons Lake, a eutrophic sand dune lake with no defined outlet. In Waihi Beach Reservoir a stocking density of 26 fish per ha resulted in a change in plant species dominance (due to preferential feeding) but no long term reduction of standing crop. A stocking density of 37-52 per ha was required to heavily reduce the aquatic vegetation over 2 summers. In Parkinsons Lake 37-44 carp per ha eliminated all vegetation by midsummer. The most palatable species were Potamogeton ochreatus and Eleocharis sphacelata. At higher stocking densities, these and Egeria densa and Nitella hookeri were virtually eliminated. A more accurate estimate of weed removal rates would result if calculated on the basis of littoral zone area or number of aquatic plants. Since the degree of weed control depends on so many factors (plant growth, fish growth, mortality rates, water temperature, and standing crop), it is difficult to determine the optimum stocking density. Removal of stocked carp was difficult. However, this is necessary if aquatic weed control growths are to be managed rather than eliminated. (Cassar-FRC)

SEEDING-OPPORTUNITY RECOGNITION IN WINTER OROGRAPHIC CLOUDS,
Utah Water Research Lab., Logan.
G. E. Hill.
Journal of Applied Meteorology, Vol 19, No 12, p 1371-1381, December, 1980. 14 Fig, 2 Tab, 18 Ref.

Descriptors: *Cloud seeding, *Weather modification, Moisture deficiency, *Artificial precipitation, Rainfall, Cloud physics, Clouds, Temperatures, Orography, Orographic precipitation.

Basic meteorological parameters used to develop the present cloud seeding hypothesis for winter orographic storms are: cloud-top temperature, updraft speed, supercooled liquid water concentration, and precipitation rate. Analysis of supercooled water concentrations and precipitation as functions of cloud-top temperature and orographic updraft speeds indicates that seedability is marked by cloud-top temperatures from minus 22 degrees to zero degrees C and updraft speeds of 1 mile/second or greater. This hypothesis is substantiated by taking aircraft icing reports as representing supercooled water concentrations, and taking cross-barrier flow as representing vertical motion. The potential precipitation yield increases as the square of the cross-barrier wind speed increases within the suitable cloud-top temperature range. About 20% of the winter orographic clouds offer such high potential. High seedability is expected to be associated with post-frontal conditions where the cross-barrier flow is strong, high-level subsidence is occurring, and the moisture is still high at mountaintop levels, or where weak low-level moisture systems are moving with strong airflow. 3C. Use Of Water Of Impaired Quality

RECYCLING URBAN STORMWATER FOR PROFIT,
Environmental Protection Agency, Edison, NJ.
R. Field, and C-Y. Fan.
Water/Engineering and Management, Vol 128, No 4, p 30-33, April, 1981. 2 Fig, 6 Tab, 25 Ref.

Descriptors: *Storm runoff, *Reclaimed water, *Water reuse, *Urban runoff, Storm water, Combined sewer overflows, Wastewater treatment, Industrial water.

Current urban storm water control and treatment technology leading to its reuse in industrial cooling and processes, irrigation, and recreational water supply are presented. Although storm water pollutant concentration varies with time and location during a storm and from one storm to another, the BOD5 is usually close to that of municipal sewage secondary effluent, and the suspended solids concentration is similar to that of raw sanitary wastewater. Combined sewer overflow quality lies between that of untreated sanitary sewage and urban storm runoff. Physical treatment units are more effective than biological systems because they can handle the highly variable flow rates and pollutant concentrations. The treatment chosen depends on the desired use: low level treatment for irrigation water and high level treatment for boiler feed water. A table lists four categories of waters, AA, A, B, and C, with the maximum concentrations of metals, anions, color, etc., allowed for each classification. A hypothetical case study of a 100 acre industrial complex illustrates the planning process. After the demand and quality requirements in each category of water quality are decided, storage and treatment facilities are designed for each class of water. Next, costs are determined. Three reuse alternatives are compared: all city water, all storm water except for potable water, and all storm water except for potable water and process water. The cheapest alternative in this case reuses stormwater for irrigation process and cooling water and gives a total water supply cost of $1.54 million, saving $800,000 over the use of city water for these purposes plus for potable water. (Cassar-FRC)

EFFECTS OF MUNICIPAL WASTE WATER EFFLUENT ON PERFORMANCE AND FEED QUALITY OF MAIZE VS. REED CANARYGRASS,
Science and Education Administration, St. Paul, MN.
G. C. Marten, W. E. Larson, and C. E. Clapp.
Journal of Environmental Quality, Vol 9, No 1, p 137-141, January-March, 1980. 5 Tab, 9 Ref.

Descriptors: *Wastewater farming, *Crop yield, *Corn, Grasses, Wastewater irrigation, Wastewater disposal, Crop production, Forages, Feeds, Fodder, Proteins.

The field quality and yields of dry matter, digestible dry matter, and crude protein of maize and reed canarygrass were determined when fields were managed for maximum yield and when irrigated with two levels of municipal wastewater effluent. The three treatments of plots were a control consisting of well water and mineral fertilizer, application of 5 cm of wastewater per week, and application of 10 cm of water per week. In the second through fourth year, the maize fodder was more digestible than any of the reed. The reed canarygrass always contained more crude protein than the maize. Seventeen to 36% more dry matter and 23 to 41% more digestible dry matter was yielded by the maize fodder. These differences

were reduced as effluent applications increased. Reed canarygrass yielded from 30 to 52% more crude protein per hectare. Thus, perennial grasses seem to have a superior capacity when compared to maize for removing nitrogen from soil treated with wastewater effluent. The grasses yielded the most protein per hectare but the least digestible dry matter when treated with effluent. (Small-FRC)

IRRIGATION AND DRAINAGE WATERS OF A NEW IRRIGATION ZONE IN THE HUNGRY STEPPE AND POSSIBILITIES OF THEIR USE,
V. A. Molodtsov.
Water Resources (English Translation), Vol 7, No 5, p 422-430, September/October, 1980. 1 Fig, 5 Tab, 5 Ref. Translated from Vodnye Resursy, No 5, p 89-99, September/October, 1980.

Descriptors: *Irrigation, *Drainage waters, *USSR, Hungry Steppe, Water demand, Chemical analysis, Mineralization, Flushing, Chemical composition, Asia, Salts, Saline soils.

An acute shortage of fresh water resources is developing in Central Asia as a result of increasing irrigation. The mineralization and chemical composition of rivers of Central Asia, especially the Syr Darya, have changed significantly since the 1950s. The increased mineralization of the Syr Darya is primarily the result of the inflow of drainage waters from the Fergana Valley. The possibility of using waters having increased mineralization for flushing saline soils has commanded considerable interest as the need for fresh water sources has become more acute. The mineralization and chemical composition of irrigation and drainage waters of the newly irrigated zone in the Hungry steppe were observed monthly for three years in an effort to determine their suitability for use in flushing operations. These studies indicated that the use of drainage waters for flushing salinized soils was feasible in three regions of the Hungry Steppe. The waters of the Central Hungry Steppe Collector Drain (CHD) could be used for flushing the area confined to the Dzhetysai and Sardobin depressions, which contain meadow solonchaks with more than 2 percent toxic salts in the upper 1 meter layer. Drainage waters from group collector drains can be used for flushing areas in the southeastern part of the Hungry Steppe, including parts of the Khavast alluvial fan and the eastern part of the Dzhizak Steppe. Waters of Central Collector Drain No. 7 can also be used to flush the peripheral territory of the Khavast alluvial fan. The waters of the collection drains of the Khavast alluvial fan and the CHD can be used to flush the territory of the Khavast alluvial fan adjacent to the Sardobin depression. Drainage waters in the territory of the Dzhiil'min part of the Dzhizak Steppe could conceivably be used for flushing if vertical drains were constructed and well discharges were large. Drainage waters in the rest of the Hungry Steppe are not suitable for flushing soils in their vicinity. (Carroll-FRC)

THE EFFECTS OF SODIUM AND ORGANIC MATTER IN SEWAGE EFFLUENT ON WATER RETENTION PROPERTIES OF SOILS,
The Hebrew Univ., Rehovot (Israel). Dept. of Soil and Water Science.
S. Burns, and E. Rawitz.
Soil Science Society of America Journal, Vol 45, No 3, p 487-493, May-June, 1981. 7 Fig, 3 Tab, 17 Ref.

Descriptors: *Soil moisture retention, *Wastewater irrigation, Soil properties, Effluents, *Organic matter, *Sodium, Moisture availability, Irrigation, Infiltration.

A set of laboratory experiments conducted to test effects of sewage effluent on the water relations of soil under simulated drop irrigation is presented. Soil used was taken from two separate depths at Kfar Kayarok in the Israeli Coastal Plain. Under the conditions of this study, no amount of sewage water approximately equivalent to one season's irrigation in the field was sufficient to increase the soil's capacity to retain water. No ponding occurred, and aerobic conditions were maintained. Allowing the soil to dry a few days between irrigations was the determining factor in preventing ponding. When using effluent for crop irrigation, as opposed to utilizing cropland for effluent disposal, the intermittent wetting and drying regime is the more representative of field conditions. Effluent sodium adsorption ratio (SAR) was instrumental in increasing the amount of water held, by deflocculating the soil. Soil drying enhanced organic matter-clay complex formation between soil clay colloids and the organic solids introduced by the sewage effluent. In finer soil, these complexes were fairly stable and produced cracking in the surface which can be useful in field water management. In coarser soil less stable, organic matter-clay complexes were formed, which were easily destroyed by simulated rain application, resulting in redispersion and soil-pore blockage by organic colloisds. (Baker-FRC)

THAMES REARS CARP IN SEWAGE.
Water, No 38, p 38, May, 1981.

Descriptors: *Fish farming, *Wastewater, Water reuse, Fish stocking, Fisheries, Fish, Carp, Wastewater lagoons, Lagoons, England.

Sewage treatment lagoons have been stocked annually with excess stocks of small fry, and these are cropped 12 months later when they have reached about 17 cm in length. This creates a secondary function for the lagoons, the rearing of fish for which all the feed is provided by the effluent, and yet which achieve a marketable value in one year. Five hundred Kg. of quality rough fish have been removed from the Stanford lagoons by sewage operators and divisional scientific staff using the electro-fishing method. Before being distributed, the fish are given a thorough health check. The screening is very thorough, as these fish then go on to healthy fisheries. A random sample from each batch is checked for any irregularities. (Baker-FRC)

SALINE WATER USE AND DISPOSAL OPPORTUNITIES; COLORADO RIVER WATER QUALITY IMPROVEMENT PROGRAM,
Bureau of Reclamation, Boulder City, NV.
Special Report, Sepember, 1981. 153 p, 20 Fig, 31 Tab, 50 Ref, 4 Append.

Descriptors: *Saline water, *Impaired water use, *Cooling water, *Waste water disposal, Coal slurry pipelines, Saline water systems, Industrial water, Fuel, Solar energy, *Colorado River basins.

Saline concentrations in the Colorado River are increasing and will continue to increase as the Basin States develop their lands and available water resources. Without a program of salinity control, continued development will result in increased damages to agricultural, municipal, and industrial users. An assessment was made of the potential technical and economic feasibility of collecting saline water in the Colorado River Basin, transporting it for practical use in energy production, and exporting and disposing of wastewater in a cost-effective manner. Sixteen saline water sources were evaluated in various collection configurations for local use or export. The total water volume considered as potential sources for use or disposal is 610,000 acre-feet. Efforts were directed to highlighting opportunities of using saline water in powerplant cooling and industrial processing as well as coal slurry pipelines. The most promising beneficial use cases appear to be: local use of saline water for powerplant cooling; and a coal slurry pipeline carrying 50 or 100 million tons of coal per year to southern California using saline water as the transport medium. Other potential uses include salt gradient solar ponds for desalting and power generation. Wastewater and blowdown collection and disposal service were also examined for energy development sites located near saline water pipeline collection systems. If a long-distance pipeline is developed for other purposes, economies of scale may make wastewater collection and disposal a viable alternative. (Moore-SRC)

QUALITY OF IRRIGATION WATER AND EFFECTS OF SULFURIC ACID AND GYPSUM ON SOIL PROPERTIES AND SUNDANGRASS YIELDS,
Arizona Univ., Tucson. Dept. of Soils, Water, and Engineering.
B. J. Alawi, J. L. Stroehlein, E. A. Hanlon Jr, and F. Turner Jr.
Soil Science, Vol 129, No 5, p 315-322, May, 1980. 2 Fig, 1 Tab, 6 Ref.

Descriptors: Saline soils, *Sulfuric acid, *Gypsum, *Irrigation effects, Irrigation water, *Soil properties, *Crop yield, Infiltration rate, Sudangrass.

A study is presented which was designed to show the effects of continuous irrigation with waters of different qualities on soil properties and crop yields. Also, the extent to which relatively low rates of sulfuric acid and gypsum can be used beneficially to reduce soil salinity and sodium and improve infiltration rates and crop yields was determined. Plots were irrigated over a three year period with water which had a salinity content varying from ECw of 3.2 times 10 to the 3rd power to 0.55 times 10 to the 3rd power millimhos/cm. Different soil slainities resulted, and the exchangeable sodium percentage ranged from 18.4 to 24.0 in the surface 30 cm of soil. Over a two year period, Sudangrass yields increased with decreasing water salinity after the addition of relatively low rates of 93% H2S04 and gypsum. Yields were increased by H2S04 and gypsum with all three waters the first year, but only by H2S04 the second year. Thus, sulfuric acid was generally superior to gypsum for reducing soil salinity and exchangeable sodium percentage. (Small-FRC)

2,500 ACRES OF WASTEWATER IRRIGATION,
J. F. Blair.
BioCycle, Vol. 22, No 3, p 30-31, May/June, 1981.

Descriptors: *Irrigation water, *Wastewater irrigation, Water reuse, Agriculture, Pipelines, Water conveyance, Water storage, Lubbock, Texas.

Near Lubbock, Texas, 7.2 mgd of treated wastewater pumped through a 16 mile pipeline will irrigate 2500 acres of cropland. At the end of the 27 inch watertight pipeline are three 15 inch lines leading to earthen storage lagoons, each 50-100 acres in area and 13 ft in depth. From the lakes, water is pumped through center pivot sprinkler systems. It is expected that cotton production will increase to 1.5 bales per acre from the nonirrigated yield of 0.5 bales per acre. Forty years' experience with wastewater irrigation on the nearby 4,000 acre Gray farm have shown that seepage never reached below 15 ft and did not enter the Ogallala aquifer. (Cassar-FRC)

GROWTH OF THE BAY SCALLOP, ARGOPECTEN IRRADIANS, IN A WASTE RECYCLING AQUACULTURE SYSTEM,
Woods Hole Oceanographic Institution, MA.
R. Mann, and R. E. Taylor, Jr.
Aquaculture, Vol. 24, No. 1/2, p 45-52, May, 1981. 2 Fig, 1 Tab, 14 Ref.

Descriptors: *Water recovery, *Aquaculture, *Recycling, Mollusks, *Aquatic animals, *Scallops, Wastewater treatment, Water quality, Growth, Impaired water use.

This report presents results of studies of the growth of Argopecten irradians both in a pilot scale waste recycling aquaculture system, and in laboratory systems at four temperatures when fed on phytoplankton cultured in sewage-seawater mixtures. Juvenile A. irradians were grown successfully on a diet of phytoplankton cultured in sewage-seawater mixtures. A. irradians increased from initial live and dry meat weights of 1.15 g and 0.043 g respectively, to terminal values of 9.08 g and 0.599 g, respectively. This corresponds to instantaneous growth rates for live weight and dry meat weight of 0.009 and 0.013, respectively. High mortalities were evident towards the end of the experiment, with a terminal value of 33%, giving an instantaneous mortality rate value of 0.0016. In laboratory experiments of 12 weeks in length at 12, 15, 18 and 21 degrees C, juvenile A. irradians gave values of 0.01, 0.013, 0.018, and 0.016 for live weight, 0.015, 0.015, 0.016, and 0.013 for dry weight and 0.038,0.038, 0.037 and 0.040 for instantaneous mortality rate at the respective temperatures. A. irradians exhibited specific growth rates comparable to or higher than those previously recorded for other bivalve species cultured in waste recycling systems. However, a considerable reduction in the presently high mortality rate will be needed to make A. irradians a prime candidate for practical application. (Baker-FRC)

ENVIRONMENTAL EFFECTS OF WATER REUSE SCHEME,
Sewage Reclamation Dept., Tel Aviv (Israel).
E. Idelovitch.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE3, p 561-570, June, 1980. 4 Fig, 4 Tab, 7 Ref.

Descriptors: *Wastewater renovation, *Environmental effects, *Water reuse, *Israel, Water supply, Water demand, Water resources development, Water treatment facilities, Wastewater treatment.

Due to the scarcity of water supplies in Israel, it is not feasible to discharge wastewater into the sea. First, such discharge would be environmentally unsound. Second, the wastewater should be treated for reuse as a source of supply for agricultural, industrial, and even municipal consumers. The Dan Region Project in the Tel Aviv Metropolitan Area is the largest and most advanced water reuse scheme in Israel. The first stage of the project, now in operation, comprises facilities for advanced treatment and groundwater recharge of wastewaters discharged from the Southern Tel Aviv Metropolitan Area. These facilities serve a total population of about 400,000 and have a capacity of 20,000,000 cubic meters per year or about 15 mgd. The second part of the project deals with wastewater from the northern and eastern parts of the Tel Aviv Metro Area. Prior to the completion of the first stage, most of the wastewater which is now treated had been discharged into the Mediterranean Sea. The water now undergoes biological and physicochemical treatment, and is then recharged to the groundwater aquifer by intermittent spreading over sand basins. The reclaimed water will be used to supplement nonpotable needs. The oxidation ponds in the first stage remove settleable solids, sand, suspended solids, soluble biodegradable matter, nitrogen, and heavy metals, within a process of algae growth. A high lime-magnesium process removes suspended solids, bacteria, viruses, and some inorganic dissolved solids. The polishing ponds provide for stripping of free ammonia at high pH and for recarbonation of the lime treated effluent by absorption of carbon dioxide. (Baker-FRC)

EFFECTS OF WATER QUALITY ON FORAGE PRODUCTION,
Texas Tech Univ., Lubbock. Dept. of Plant and Soil Science.
R. E. Zartman, T. D. Miller, J. R. Goodin, and M. Gichuru.
Journal of Environmental Quality, Vol 9, No 2, p 187-190, April/June, 1980. 4 Tab, 15 Ref.

Descriptors: *Cooling water, *Irrigation effects, *Forages, Irrigation water, Water quality, Crop yield, Alfalfa, Municipal water, Water reuse, Electric powerplants, Crop production, Lubbock, *Texas.

The effects of water quality on forage production were investigated in a 4-yr field study conducted at the Jones Station Facility in Lubbock, Texas. Three application rates (high, medium, and low) of electric powerplant cooling water and city water were used to irrigate fourwinged saltbush (Atriplex canescens) and alfalfa (Medicago sativa) stands started on a Friona fine sandy loam in 1975. Alfalfa crops reacted favorably to irrigation, with the highest yields occurring in the high-irrigation city water treatment, followed by the high irrigation blowdown water treatment. Alfalfa stands receiving medium irrigation levels produced moderate yields, while the dryland production decreased during the course of the experiment. Irrigation had little effect on yields of Atriplex stands. No differences in forage yield were found between fields irrigated with city and cooling water. It was concluded that alfalfa production benefits by irrigation with either blowdown or city water. (Geiger-FRC)

HEALTH ASPECTS OF URBAN WATER CONSERVATION,
East Tennessee State Univ., Johnson City. Dept. of Environmental Health.
C. S. Bishop, and V. A. Sikora.
Journal of Environmental Health, Vol 42, No 5, p 250-252, March/April, 1980. 1 Ref.

Descriptors: *Water demand, *Conservation, Water supply, Water supply development, *Water reuse, Potential water supply, Water shortage, *Public health, Urban areas.

The nature, potential scope and limitations of the federal urban water conservation program in relationship to environmental health are considered. As demand for additional water supplies grows, conservation becomes increasingly important. Environmental health professionals must help insure that a comprehensive approach will be taken and that forthcoming innovations will not jeopardize the public health. Approaches to decrease the consumption of water include reducing pressure in the distribution system, use of water saving devices, reducing leakage, in-home wastewater recycling systems, and increased water prices. Each of these possibilities has potential problems which must be understood before they are undertaken. A great deal of controversy exists concerning reusing wastewater in the home. The concept of a split system in which water used for washing is then used for toilet flushing is interesting. However, it may lead to cross connection and the potential for contaminated water to enter the potable water supply, creating a health hazard for a large number of people. Any such water saving devices will probably be installed as a novelty and will not be used uniformly throughout a system. They may then be misused by subsequent owners of a home or by tenants. Building inspectors view this as a potential problem. (Baker-FRC)

3E. Conservation In Industry

GROUND-WATER USE FOR COOLING: ASSOCIATED AQUIFER TEMPERATURE CHANGES,
California Univ., Berkeley. Lawrence Berkeley Lab.
M. J. Lippman, and C. F. Tsang.
Ground Water, Vol 18, No 5, p 452-458, September/October, 1980. 4 Fig, 3 Tab, 11 Ref.

Descriptors: *Cooling water, *Injection wells, *Electric powerplants, Aquifer management, Powerplants, *Water conservation, Thermal pollution, Heated water, Groundwater.

Water and energy conservation could result if cooling waters from a steam-electric plant are injected into an aquifer for later use in heating, industry, or agriculture. This paper analyzed a simple system comprising one withdrawal and one injection well and concluded that, at rates of 3.65 million cu meters per year, the wells are usable for 2 to 8 years before the temperature of the extracted water becomes too hot to produce a cooling effect. In actual field use a much larger number of wells would be used, extending the life of the well field. The heating effects in confined aquifers are localized around the injection wells. When well operation ceases, the hot water plume drifts in the direction of the groundwater flow, gradually cooling. (Cassar-FRC)

3F. Conservation In Agriculture

SALINE IRRIGATION WATER.
World Farming, Vol 23, No 1, p 24, January/February, 1981.

Descriptors: *Saline water, *Irrigation practices, *Sprinkler irrigation, Water injury, Water pollution effects, Salt tolerance, Irrigation efficiency.

Sprinkling irrigation water during the evening or night can reduce leaf salt absorption by half compared with daytime sprinkling. Irrigation should be infrequent and heavy, with sprinkler rotations of 1 min or less to prevent drying between cycles. As little as 200 ppm of salts in irrigation water can injure crops if leaves accumulate salt. Furrow or flooding irrigation causes less salt injury than sprinkler irrigation for the more sensitive crops: citrus, stone fruit trees, almonds, peppers, potatoes, tomatoes, alfalfa, barley, safflower, sesame, and sorghum. YIELD AND WATER USE OF VEGETABLE CROPS WITH SEEPAGE AND DRIP IRRIGATION SYSTEMS,
Agricultural Research and Education Center, Bradenton.
A. A. Csizinszky.
Florida Scientist, Vol 43, No 4, p 285-292, Fall, 1980. 1 Fig, 6 Tab, 6 Ref.

Descriptors: *Irrigation efficiency, *Vegetable crops, *Water use efficiency, Corn, Broccoli, Squash, Drip irrigation, Seepage, Crop yield, Water conservation, Conservation.

The effects of seepage and drip irrigation on crop yield were studied in spring 1978 on broccoli (Brassica oleracea L., Italica Group cv. 'Green Comet Hybrid'), sweet corn (Zea mays cv. 'Silver Queen'), and zucchini squash (Cucurbita pepo cv. 'Fordhook'). Yields per plant in kg (seepage and drip, respectively) were: broccoli, 0.307 and 0.198; corn, 0.191 and 0.189; and zucchini, 6.13 and 6.32. Plant densities for seep irrigation were 70-85% of the densities for drip irrigation. Yields per hectare in tons (seepage and drip, respectively) were: broccoli, 3.76 and 3.15; corn, 10.68 and 12.14; and zucchini, 45.21 and 60.67. Seepage irrigation plots received water at a constant rate of 13.31 liters per sq meter per day, and the amount of water with the drip system was adjusted every 10 days. Total amounts of water received during the growing season in liters per sq meter (seepage and drip, respectively) were: broccoli, 752 and 216; corn, 978 and 355; and zucchini, 1124 and 359. Water use (in liters) to produce 1 kg of marketable yield were: broccoli, 1999 and 684; sweet corn, 916 and

193; and zucchini, 249 and 59, for seepage and drip irrigation, respectively. (Cassar-FRC)

TRAVELING SPRINKLER SYSTEM AND METHOD,
Toro Co., San Marcos, CA. (Assignee).
E. J. Hunter.
U.S. Patent No 4,204,642, 33 p, 43 Fig, 8 Ref; Official Gazette of the United States Patent Office, Vol 994, No 4, p 1260-1261, May 27, 1980.

Descriptors: *Patents, *Irrigation systems, *Sprinkler irrigation, *Application equipment, Irrigation efficiency, Irrigation practices, Irrigation operation and maintenance.

A low capital investment system for irrigating a relatively large area field, comprises a mobile base, and a sprinkler mounted on the base and adapted to accumulate water from a water supply and to intermittently discharge the accumulated water in a stream over the field. Apparatus is provided for propelling the base in a back and forth movement traversing a field, and for generally reversing the water discharge direction each time the direction of travel is reversed. The sprinkler includes a resiliently expandable reservoir construction for accumulating relatively large volume, intermittent bursts, and a drive system which also provides relatively short range, continual irrigation. Separate sprinkler units can be used on a field concurrently, or a single unit can be moved over successive areas of a field until the whole field has been covered. The system may also be combined with a center pivot device to irrigate land that would otherwise be unused. (Sinha-OEIS)

RESEARCH AND DEVELOPMENT TO SERVICE A SUSTAINABLE AGRICULTURE,
University of New England, Armidale (Australia).
J. R. McWilliam.
Search, Vol 12, No 1/2, p 15-21, January/February, 1981. 5 Fig, 16 Ref.

Descriptors: *Research priorities, *Irrigation efficiency, *Dry farming, Irrigation, Water use efficiency, Water management, Water resources development, *Australia.

Important problems which threaten the stability of Australia's irrigated and dry-land cropping systems are considered and the most urgent research needs are identified. The originality and effectiveness of research depends upon the quality of students and the agricultural education available to them. A successful utilization of Australia's water and soil resources depends on efficient conservation and management practices. Research is needed in the area of irrigation. Most of the water resources are located in the north, where only about 5% of available water is utilized. In the south, where irrigation is used, there are problems with the buildup of salinity and the deterioration of structure in fine-textured soil under intensive cropping. Efficient water management is especially important in areas which employ dryland cropping. Research is needed on the effects of tillage, including no-till, minimum tillage, and various forms of stubble retention and mulching. Research is also needed in crop development, past and pathogen control, and the establishment of pastures. (Small-FRC)

OPERATIONAL EVALUATION OF VILLAGE LEVEL IRRIGATION CONVEYANCE SYSTEMS,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
T. J. Trout, and S. A. Bowers.
Transactions of the ASAE, Vol 24, No 3, p 636-642, May/June, 1981. 9 Fig, 5 Tab, 7 Ref.

Descriptors: *Conveyance structures, *Water loss, *Irrigation ditches, Water conveyance, Leakage, Irrigation operation, Mathematical studies, Design criteria, *Pakistan.

In a study of five village level watercourse systems in Pakistan, total operational conveyance losses were measured using an adaptation of the inflow-outflow method. The extents of transient losses were quantified, as were the types of watercourse losses, to aid in the evaluation of conveyance efficiencies. Flow rates were monitored continuously, and flow hydrographs were created. Operational losses were calculated as the difference between the volume of water entering the watercourse at the head and the volume entering the irrigated fields. Total losses varied from 37 to 56%, and averaged 45% on inflow. Fifty-five percent of the losses occurred on the primary channels. Less than 1% of the losses were attributed to evaporation, and loss rates decreased with distance. Seven percent of the inflow or 15% of the losses were due to transient phenomena such as wetting dry channels, dead storage, and short-term breaches. Steady-state seepage into channel wetted perimeters was much greater than would be expected from normal infiltration. (Small-FRC)

LAND FORMING EFFECTS ON DRYLAND SORGHUM PRODUCTION IN THE SOUTHERN GREAT PLAINS,
Science and Education Administration, Bushland, TX. Conservation and Production Research Lab.
O. R. Jones.
Soil Science Society of America Journal, Vol 45, No 3, p 606-611, May-June, 1981. 4 Fig, 5 Tab, 10 Ref.

Descriptors: *Crop yield, *Cultivation, Soil moisture retention, Soil water, Moisture availability, Agriculture, Erosion, Water conservation, *Sorghum, Runoff control, *Land forming.

Research was conducted to develop low-cost land forming systems for controlling or reducing storm runoff on drylands and to determine the effectiveness of selected land forming systems in preventing runoff, controlling erosion, storing water, and increasing grain sorghum yields. Various land forming treatments investigated included conventional graded furror, conventional contour furrow, wide furrow, Orthman, mini-bench, and conservation mini-bench. All plots were tandem-disked about 0.07 meters deep in early April each year to bury residue and allow volunteer sorghum to sprout. Furrow treatments were imposed in early May. Conventionally constructed contour furrows on large fields frequently overtop during heavy, high-intensity rainstorms. Overtopping and subsequent soil erosion from runoff results when the surface-water storage capacity of furrows or border dikes is exceeded. Orthman, wide furrow, mini-bench, and conservation mini-bench treatments did not overtop but retained all precipitation from this record rainstorm because their surface-water capacity was not exceeded. Thus level land forming systems can effectively conserve precipitation and prevent runoff on large, gently sloping field areas in the Southern Great Plains. Water is the limiting resource for crop production in the area. Approximately one half of the total water requirements for a dryland sorghum crop can be provided from soil water stored at seeding time. Land leveling is the most effective conservation practice for preventing runoff and increasing dryland crop yields. (Baker-FRC)

EFFECT OF SOIL WATER CONTENT AND A GROWING SEASON STRAW MULCH ON GRAIN SORGHUM,
Science and Education Administration, Bushland, TX. Conservation and Production Research Lab.
P. W. Unger, and O. R. Jones.
Soil Science Society of America Journal, Vol 45, No 1, p 129-134, 1981. 2 Fig, 1 Tab, 14 Ref.

Descriptors: *Mulching, *Sorghum, *Soil water, Straw, Mulches, Crop production, *Crop yield, Water use efficiency, Soil moisture retention.

A study was performed to evaluate the contribution of a growing season straw mulch to grain sorghum growth, yield, grain quality, water use, and water use efficiency. Plots of Pullman clay loam were given two irrigations, one irrigation, and no irrigation prior to planting in order to simulate high, medium, and low levels of water storage in soil during fallow. Zero, 2, 4, or 8 metric tons of wheat straw per hectare were placed on the surface after the sorghum emerged. Sorghum responses to the high and medium water storage levels were similar, since the second irrigation resulted in relatively little additional storage due to the slow permeability of the soil. However, sorghum on plots receiving one or two irrigations grew taller, yielded more, and used water more efficiently than water on unirrigated plots. In general, sorghum responded more to soil water content at planting than to mulch rate during the growing season. Over a three year period, application of 8 metric tons of straw per hectare during the growing season resulted in a 19 percent increase in water use efficiency over plots receiving no mulch. Shading from the plant canopy appeared to provide the beneficial effect of a mulch during the growing season. A major beneficial effect of using a mulch during both the fallow and the growing seasons, in terms of water conservation and crop production, is the enhancement of water storage in the soil during fallow periods. (Carroll-FRC)

SIZING RICE IRRIGATION CANALS,
D. P. Spare, J-K. Wang, and R. E. Hagan.
Transactions of the ASAE, Vol 23, No 4, p 914-918, 923, July/August, 1980. 1 Fig, 3 Tab, 3 Ref.

Descriptors: *Rice, *Irrigation canals, *Design criteria, Flood irrigation, Cropland, Canals, Irrigation design, Mathematical studies, Mathematical equations.

The peak demand for irrigation water in a paddy rice production system, which occurs at the beginning of a production season when land soaking water is introduced, determines the sizes of irrigation canals needed. Three conflicting requirements must be suitably reconciled if this peak water demand is to be minimized. First, the system-wide water demand during the land soaking period should follow as closely as possible the theoretical minimum values proposed by Hagan and Wang (1977). Second, the minimum land area to be served by a given sublateral or farm-ditch during a rotational period should not be less than that determined by local circumstances. Third, the patterns of subdivision of the project area into command and service areas to be served by laterals and farm ditches which are dictated by topographical and sociological constraints should be respected. A procedure for the design of sublateral in-field irrigation water distribution systems for paddy rice production systems which reconciles these three requirements is presented. The procedure minimizes the peak water requirement of the produc-

tion system and gives a detailed irrigation schedule for the land soaking period. The procedure has been applied to the design of the Naga-Calabanga Integrated Agricultural Development Area project, a 7,000 hectare paddy rice production system in the Philippines. (Carroll-FRC)

WATER REQUIREMENT FOR SUGARCANE PRODUCTION,
Agricultural Research and Education Center, Belle Glade, FL.
S. F. Shih, and G. J. Gascho.
Transactions of the ASAE, Vol 23, No 4, p 934-937, July/August, 1980. 4 Fig, 3 Tab, 19 Ref.

Descriptors: *Crop production, *Water requirements, *Sugarcane, Sugar crops, Water use, Rainfall, Lysimeters, Soil water, Soil-water-plant relationships.

The only economically feasible strategy for increasing the longevity of the organic soils of the Everglades, which are subsiding at a rate of between 1.5 and 3.1 centimeters per year, is to maintain high water tables. However, available data on the effect of water table level on water requirement and production performance of sugarcane are not adequate for making precise recommendations as to optimum water table depth for sugarcane production and soil conservation. Six lysimeters were used to control water tables at 30, 60, and 90 centimeters below the muck soil surface for sugarcane production. The effective rainfall was found to be proportional to water table depth, with about 3.4 centimeters of rainfall stored in the soil for each 10-centimeter increment of water table depth. Water table depth had a significant effect on water requirement in both the dry and the grand growth periods. Each 10-centimeter increase in water table depth resulted in a reduction in the water requirement of about 3.7 centimeters for plant crop and 2.2 centimeters for ratoon crop during the dry season and about 3.4 and 1.3 centimeters, respectively, during the grand growth period. Maintaining a high water table will increase the requirements for water for irrigation and the need for pumping for drainage following heavy rainstorms. The water required to produce 1 kilogram of fresh cane varied from 89 kilograms in plant crops to 118 kilograms in the ratoon crop. Water requirements for production of 1 kilogram of sugar ranged from 884 kilograms in plant crop to 1115 kilograms in ratoon crop, indicating lower water use efficiency by ratoon crop. (Carroll-FRC)
W82-00899

DEPTHS OF FLOW IN LEVEL BASINS,
Science and Education Administration, Phoenix, AZ. Water Conservation Lab.
A. J. Clemmens.
Transactions of the ASAE, Vol 23, No 4, p 910-913, July/August, 1980. 1 Fig, 1 Tab, 7 Ref.

Descriptors: *Water depth, *Basins, *Flow rates, Border irrigation, Irrigation, Infiltration, Mathematical studies, *Basin irrigation, Level basins.

The design of level basins is based on balancing the infiltration characteristics of the soil, the basin size, and the available irrigation stream (flow rate). Since the use of the largest possible stream available can cause excessive surface water depths in some cases, the design of level basins can also be dependent upon a practical limit on basin ridge or border height. A solution for the maximum surface water depth in level basins was developed from the zero-inertia border irrigation model developed by Strelkoff and Katopodes (1977). This model is based on continuity and momentum principles. The solution is applicable to rectangular basins irrigated from one end where the application time is less than the advance time to the end of the basin. A direct comparison of the solution results with the design charts in the Soil Conservation Service Border Irrigation Handbook demonstrates that the solutions presented in these charts can be in error by as much as 20 percent within a realistic range of field variables. THE UNCERTAINTY OF CROP MODELS IN IRRIGATION OPTIMIZATION,
Oregon State Univ., Corvallis. Dept. of Agricultural Engineering.
M. J. English.
Transactions of the ASAE, Vol 24, No 4, p 917-921, July/August, 1981. 6 Fig, 2 Tab, 10 Ref.

Descriptors: *Model studies, *Irrigation practices, Crop yield, Simulation, Weather, *Optimization, Irrigation efficiency.

This paper is concerned with economic optimization of irrigation practices. Optimization is taken to mean maximizing the net benefit realized from the unit of water used. Crop production models are considered which relate applied water to crop yield. It is noted that the relationship between the water applied and crop yield is characterized by substantial and largely unavoidable uncertainty, which may be so great as to influence a farmer's irrigation practices. A case study is presented in which the uncertainty of yield predictions is simulated for a situation involving irrigation of beans and sugar beets in southern Idaho. The consequences of that uncertainty are evaluated through the use of decision theory. A need for a probabilistic approach to crop modelling is demonstrated. Weather conditions are unpredictable. Irrigation efficiency is another source of considerable uncertainty. Crop models are needed which not only predict most probable yields, but also quantify the uncertainty in yield predictions. New models will need to emphasize statistical simulation techniques, and since statistical simulation usually involves large blocks of computer time, these models should be designed with computational efficiency in mind. The related research in agronomy, meteorology, soil science and engineering should be as concerned with variability of results as with central tendencies. Researchers concerned with water use and crop yield models need to develop an understanding of the practical applications of the variability and uncertainty of such models. (Baker-FRC)

LATERAL SIZES FOR EFFICIENT LEVEL-BASIN IRRIGATION,
Agricultural Research Service, Fort Collins, CO.
E. G. Kruse.
Transactions of the ASAE, Vol 24, No 4, p 961-967, 969, July/August, 1981. 3 Fig, 4 Tab, 2 Ref.

Descriptors: *Irrigation practices, *Computer programs, Irrigation efficiency, Level basins, Irrigation programs, Irrigation canals, *Grand Valley, Colorado.

A procedure is described whereby a computerized data base of irrigated fields in a section of the Grand Valley was sorted to determine those fields with deep enough soils and mild enough slopes for practical basin leveling. Level-basin irrigation is an old technique for applying water to the land for the benefit of crops. There is no runoff in such a situation, and crops such as rice are easily kept inundated. Pilot studies demonstrated that with proper management, irrigation water can be applied efficiently and good crop production obtained. The computer screens data on physical characteristics of irrigated fields and then uses Soil Conservation Service design procedures to predict the necessary irrigation flows for efficient level-basin applications. The United States Water and Power Resources Service is formulating designs for improved canals, laterals, and turnouts in a pilot area of the Grand Valley. The computer program compared required delivery rates for level-basin irrigation with turnout capacities, based on existing WPRS criteria. Those turnouts which need enlargement were thus identified. Arrangements were negotiated with WPRS to increase the sizing on critical turnouts. If level-basin procedures continue to show promise of increased irrigation efficiencies and if they are adopted widely on the pilot area, this procedure will receive widespread use in planning for the remainder of the Grand Valley and other irrigated areas in the upper Colorado River Basin. WATERTABLE MANAGEMENT SAVES WATER AND ENERGY,
Science and Education Administration, Mandan, ND. Northern Great Plains Research Center.
L. C. Benz, E. J. Doring, and G. A. Reichman.
Transactions of the ASAE, Vol 24, No 4, p 995-1001, July/August, 1981. 4 Fig, 7 Tab, 15 Ref.

Descriptors: *Irrigation efficiency, *Water table, Crop yield, Water table fluctuations, Water level fluctuations, Lysimeters, Groundwater movement, Farming, Corn, Sugarbeets, Water conservation, *North Dakota.

Water and energy savings possible by maintaining shallow watertables were investigated. The field expriment was conducted near Oakes, North Dakota, on soils of the Hecla-Arveson-Fossum Association. Soil textures range from sandy loams to loamy sands in the surface but have uniformly sandy subsoils. Corn and sugarbeets were grown for 3 years with four applied water treatments, three imposed water tables, and four replications. As it was impossible to maintain the watertable at prescribed depths in the field experiment, twelve nonweighing lysimeters were constructed near the field plot experiment. In the field plot studies where the growing season 3-year average watertables were 1.5, 2.1, and 2.4 meters deep, yields of corn grain, corn total dry matter, sugarbeet roots, and sugarbeet sucrose were higher with the 1.5 meter watertable than with the deeper watertables irrespective of irrigation water applied. Thus irrigation water and energy were wasted where the shallow watertable existed. For the 2.1 and 2.4 meter watertable depths, irrigation increased yields, but maximum yields never exceeded yields obtained with the shallow watertables. The lysimeter studies included a wider range of watertable depths than field plot experiments. At the shallowest watertable, crop yields were depressed. Regression analyses of normalized field and lysimeter data indicated that maximum yields were obtained with much less irrigation water when the watertable depth was about 1.3 meters than with deeper watertables. It was concluded that a managed shallow watertable is a valuable agricultural resource that can save significant amounts of irrigation water and energy. (Baker-FRC)

DRYLAND CROPPING STRATEGIES FOR EFFICIENT WATER-USE TO CONTROL SALINE SEEPS IN THE NORTHERN GREAT PLAINS, U.S.A.,
Science and Education Administration, Mandan, ND. Northern Great Plains Research Center.
A. L. Black, P. L. Brown, A. D. Halvorson, and F. H. Siddoway.
Agricultural Water Management, Vol 4, No 1/3, p 295-311, 1981. 5 Tab, 41 Ref.

Descriptors: *Water supply development, *Cropland, *Salinity, Farming, Wheat, Sunflower, Alfalfa, Water quality, Groundwater, Water resources development, Soil water, *Seepage control, *Soil-water-plant relationships.

Soil, water, and crop management strategies needed for the control of saline seeps are identified. These strategies are based on the specific water requirements and rooting depths of crops, soil water conservation and storage, crop residue management, disease and weed control and proper fertilization. Specific strategies considered include water conservation, cropping systems, weed control and residue management. Several conclusions were reached. The practice of summer fallowing a given field every other year restricts a farmer to a fixed cropping system with limited flexibility for adjusting cropping patterns to fit available water supplies. Summer fallow should be used judiciously instead of as a regular practice. Of great importance is an understanding of the quantity and depth of available water stored within the effective rooting zone in the recharge area to be cropped. Once the quantity and depth of available soil water are known, the crop best suited to a given supply of water can be selected. On deep soils, alfalfa can remove more soil water than any other adaptable crop in a 3 to 5 year period to depths of 6 meters if no root restricting factors are present. Second in

soil water use is biennial sweet clover. Of annual crops, safflower uses the most, followed in order by sunflower, winter wheat, rapeseed, spring wheat, spring barley, and corn. After available soil water is depleted to the maximum depth possible, a flexible cropping system can be employed. Methods of weed control plus provisions for snow management, leaving crop stubble standing or establishing tall wheatgrass barrier systems to trap and hold snow, all augment available water supplies. AQUATIC WEED CUTTING APPARATUS,
J. R. McClure.
U.S. Patent No 4,205,507, 13 p, 8 Fig, 13 Ref; Official Gazette of the United States Patent Office, Vol 995, No 1, p 44, June 3, 1980.

Descriptors: *Patents, *Aquatic weed control, *Equipment, *Channel improvement, Floating, Water quality control, Weed cutter.

A floating aquatic weed cutting apparatus is disclosed which is highly maneuverable and particularly useful for cutting along banks and around obstacles. The cutter bar is entirely outward of one of the lateral sides of a flotation device. The cutter bar may be moved about an axis parallel to the central axis of the flotation device to change the angular disposition of it for cutting along submerged banks and around obstacles in the water. The entire cutter may be elevated with respect to the flotation device to raise or lower it from or into the water. (Sinha-OEIS)

THE CASPIAN SEA PROBLEM,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
D. Ya. Ratkovich.
Water Resources (English Translation), Vol 7, No 5, p 393-402, September/October, 1980. 4 Tab, 20 Ref. Translated from Vodnye Resursy, No 5, p 5-20, September/October, 1980.

Descriptors: *Caspian Sea, *Water resources development, *Resources management, Water management, Planning, Management planning, River basin development, Irrigation, Hydroelectric power, Salinity, Fisheries, Hydrologic budget, Mathematical studies, Interbasin transfers.

The Caspian Sea is the world's largest closed water body, collecting water from an area of about 3 million square kilometers. The Volga River accounts for about 75% of the total natural inflow to the sea. Although the average salinity of the sea is stable, that of the North Caspian, which is freshened by the runoff from the Volga, varies considerably. The various branches of the economy place conflicting demands on the regime of the Caspian and of the rivers flowing into it. Planned irrigation projects will decrease the runoff of the Volga, Kura, and Ural rivers, reducing the energy produced by hydroelectric stations and the depth of navigation channels. Efforts to maintain the water flow for these purposes necessitates reduction of the height and duration of floods, which will adversely affect spawning conditions of sturgeon. Reduction of the inflow into the sea results in increased salinity and may induce a drop in the water level. The water management balance of rivers of the Caspian basin is already under stress. The planned diversion of waters to the Volga from rivers and lakes of the northern European U.S.S.R. should be correlated with the rate of development of irrigation in order to preserve the unique biological productivity of the sea, to prevent the unfavorable effect of drying of the North Caspian on the climate, and to reduce losses which would result from a drop in the water level of the sea. Diversion of small amounts of water from the Volga to the Ural river would have favorable effects on the North Caspian, freshening its waters and enriching its biogenic substances. Changes which will occur in the natural conditions in zones from which water is withdrawn, and problems which may result from these changes, should be carefully considered when planning interbasin water transfer projects. BACKFILL ALTERATION EFFECTS ON PIPE DRAINAGE OF A CLAY SOIL,
Ohio Agricultural Research and Development Center, Wooster.
G. S. Taylor, S. S. Hundal, N. R. Fausey, and G. O. Schwab.
Soil Science Society of America Journal, Vol 45, No 3, p 611-616, May-June, 1981. 5 Fig, 12 Ref.

Descriptors: *Subsurface drainage, *Backfill, Permeability, Clays, Infiltration, *Drainage, Effects, *Pipes, Drawdown.

A highly permeable region was created directly over drains installed a number of years earlier in a soil of high clay content in order to determine the effect of a highly permeable backfill on drain flow rates and to assess how long the backfill would remain highly conductive under continuous row cropping. Backfill treatments included unaltered backfill; gravel backfill, in which a trench excavated above the drain was filled with a band of crushed stone placed between plow layer and drain; or trenched and refilled, in which the trench excavated above the drain was refilled with excavated soil. The effects of backfill treatments on drain flow indicated that a permeable backfill may improve drainage for soils that have a slowly permeable subsoil. The addition of gravel increased drain flow rates by a factor of two to three during periods of ponding, but had no effect on flow rates under nonponded conditions nor on water table drawdown rates. The ponded flow rates for drains with gravel have not changed after 3 years. During the first year trenching and refilling had the same effect on drain flow rates as gravel. During the second year, the ponded flow rates declined to only 50 or 60% of those with gravel. The permeable backfill functioned as a hydraulic connector and permitted ponded water to bypass the relatively impermeable subsoil in flowing to the drain. Backfill alterations did not affect sediment concentrations in the drain water. (Baker-FRC)

MODELING HYDROLOGY AND EUTROPHICATION IN A LOUISIANA SWAMP FOREST ECOSYSTEM,
Louisiana State Univ., Baton Rouge. Coastal Ecology Lab.
C. S. Hopkinson Jr, and J. W. Day Jr.
Environmental Management, Vol 4, No 4, p 325-335, July, 1980. 5 Fig, 1 Tab, 16 Ref.

Descriptors: *Swamps, *Storm water, *Environmental effects, Model studies, Coastal marshes, *des Allemands, *Louisiana, *Eutrophication, Hydrology, Wetlands, Urbanization, Lakes, Drainage canals, Nutrients, Levees, Productivity, Estuaries, Swamp forest, Water management.

The EPA Storm Water Management Model was applied to the des Allemands swamp forest, Louisiana, to determine (1) the hydrologic changes that would result from removal of spoil banks and diversion of major agricultural canals and (2) the effects of overland flow on nutrient uptake in the ecosystem. At present, the swamp becomes impounded and discharge from the forest to he lake is slow. Simulations showed that hydraulic management could increase discharge rates to the lower estuary by 22%, increase productivity of the swamp forest by 100%, and decrease lake eutrophication by 43%. Contrary to commonly held beliefs, the results suggest that these changes can be accomplished by removing levees and upland drainage canals. This would allow upland runoff to pass through the backswamp, often as sheet flow, increasing water level fluctuations in the backswamp and decreasing fluctations in the bayous. (Cassar-FRC)

THE DECLINING GROUND-WATER RESOURCES OF ALLUVIAL VALLEYS: A CASE STUDY,
Geological Survey, Lawrence, KS.
M. Sophocleous.
Ground Water, Vol 19, No 2, p 214-226, March/April, 1981. 15 Fig, 14 Ref.

Descriptors: *Groundwater depletion, *Groundwater budget, *Water conservation, Mathematical models, Depletion, Artificial recharge, Groundwater recharge, Case studies, *Kansas.

Present and future ground water withdrawals in the area of the Pawnee Valley, Kansas, were evaluated for their impact on water resources. The depletion of the water resource in the area is documented, and a preliminary hydrologic budget for the area is calculated. Also, a mathematical model is adapted and calibrated to simulate the operation of the hydrogeologic system in order to evaluate schemes for managing the ground water resource. The average natural recharge in the area was 0.5 inch/year, and the amount of appropriated ground water in the area exceeded the natural recharge figure by about 11 times. The simulations indicated that without any additional development or without very wet periods, water level declines will continue indefinitely. To reduce water depletion it will be necessary to reduce water waste, to impose a not more than 40% saturated-thickness depletion allowance for the next several years, to impose a freeze on the number of irrigation wells, and to engage in artificial recharge. TAMPA BAY WATER GUARDED BY COMPUTER,
Camp, Dresser and McKee, Inc., Clearwater, FL.
R. N. Armstrong, and H. V. Aiken.
American City and County, Vol 96, No 6, p 33-35, June, 1981. 1 Fig.

Descriptors: *Water demand, *Water resources development, Wells, *Florida, Computers, Computer models, Computer programs, Drawdown, Water supply, Water supply development, Water distribution, Monitoring, *Groundwater management, Groundwater availability, *Tampa Bay region.

Use of a specialized, innovative computer management system has succeeded in maximizing the precious water resources on the west coast of Florida in the Tampa Bay region. The computer monitors, manages, and protects groundwater sources so that critical short-term and long-term water supply demands can be met. By quickly analyzing real-time information, the monitoring and control system developed for the Cross Bar Ranch well field greatly enhances the ability of the operator to

respond to real-time conditions in the well field. In the past it may have taken several days of trial adjustment to fine tune pumping rates to bring a well field into compliance with regulatory permits. With this system wells can be connected or disconnected rapidly as demand shifts. A model was also derived for surge analysis. While surge analysis is not new, the surge model for the Cross Bar ranch field is the most complex yet devised. This system makes possible an effective analysis of the complex system of 17, three mgd wells. It also enhanced the sizing of surge tanks throughout the well field to minimize pressure waves generated by the starting and stopping of pumps. Use of the surge model saves an estimated $70,000-$80,000. (Baker-FRC)

MANAGEMENT OF RECHARGE BASINS ON THE SOUTHERN HIGH PLAINS,
Science and Education Administration, Bushland, TX. Conservation and Production Research Lab.
O. R. Jones, D. W. Goss, and A. D. Schneider.
Transactions of the ASAE, Vol 24, No 4, p 977-980, 987, July/August, 1981. 2 Fig, 4 Tab, 8 Ref.

Descriptors: *Recharge basins, *Resources management, Recharge, Groundwater recharge, *Water management, Infiltration rate, Infiltration, Groundwater movement.

Management practices were developed for recharge basins which would prevent sealing, reduce suspended solids accumulated on the basin bottom, or permit rapid removal of the sealing layer without a drying period. These practices would increase total quantity of water infiltrated and thereby reduce the cost of artificial groundwater recharge. Six 9.1 meter square basins were excavated 1.1 meters deep with a backhoe to remove slowly permeable surface soil and expose permeable Pleistocene age pluvial sediments. These exposed sediments had a clay loam texture with moderately blocky structure and a high calcium carbonate content. Basin surface treatments and management practices for each basin included: check treatment, organic mat, flocculent, high head, variable head, and corrugated. Results showed that infiltration rates were controlled at or near the basin bottom. Suspended solids in the water supply accumulated on the basin bottom and reduced infiltration rates with time. Management practices that prevented or delayed clay-layer formation at the basin bottom were effective in maintaining high infiltration rates longer, which resulted in greater total infiltration per unit area of basin surface. Infiltration rates and total quantity of water infiltrated were highest with the high-head treatment. Application of cotton gin trash to the basin surface was another effective management practice. Total infiltration per unit area of basin surface was able to be more than doubled by using improved management pratices. The combination of high-head with either the organic mat or flocculent treatment could result in even greater recharge effectiveness than any of the treatments alone. (Baker-FRC)

ILLINOIS GROUNDWATER PROBLEMS AND NEEDS,
Illinois Environmental Protection Agency, Springfield. Div. of Land/Noise Pollution Control.
J. S. Moore.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 13-14.

Descriptors: *Groundwater management, *Groundwater pollution, *Waste disposal, *Coal mining, Groundwater availability, Hazardous materials, Grants, Technology, Administrative agencies, Administrative regulations, Policy making, Public opinion, Public participation, *Illinois.

Use of underground water for public and private supplies, industrial use, and irrigation is increasing in Illinois. Approximately 38 percent of the total state population and 82 percent of the rural populaton relied on an underground water source for drinking water as of 1970. A wide variety of activities can lead to groundwater pollution, includng waste disposal sites; improper well construction; land application of potential pollutants such as fertilizers, pesticides, and road salt; mining and quarrying; individual sewer systems; and transportation of hazardous wastes. Various control strategies are possible. Illinois should (1) examine state agency jurisdiction to identify over laps or gaps in existing regulations; (2) examine the role of non-regulatory and scientific entities in the state to ensure coordination between such programs; (3) increase public awareness of the importance of groundwater as a valuable natural resource and identify existing public values and perceptions of underground water; (4) encourage public participation in program direction and development; (5) utilize the interagency groundwater task force to increase cooperation among involved state agencies on groundwater related strategies, determine the availability of data to decision-makers and identify technological practices; and (6) continue development of a comprehensive groundwater quality management program. Funds and technology-sharing must be sought from the federal government. (Garrison-Omniplan)

GROUNDWATER POLLUTION IN KENTUCKY: A STATUS REPORT,
Kentucky Dept. for Natural Resources, Frankfort.
J. C. Thornton.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 17-21, 2 Fig, 5 Ref.

Descriptors: *Groundwater pollution, *Groundwater management, Water pollution, Karst, *Waste disposal, Hazardous materials, Poisons, Groundwater availability, Sinks, Septic tanks, Seepage pits, Underground streams, Drinking water, *Water pollution control, *Kentucky.

The Commonwealth of Kentucky has had a number or problems with contaminated groundwater, particularly related to improper waste disposal practices and to problems in oil and coal fields. Many of the existing major problem areas are located within the state's widespread areas of jointed, fractured limestone, which is very susceptible to the formation of solution channels and sinkholes. This kind of topography, known as karst, covers almost 50 percent of the state and is replete with underground streams and caves. Underground streams are particularly sensitive to contamination because they flow in channels that have a much higher velocity than normal groundwaters, and receive little or no filtration from the rock. If the contamination is stopped, these systems will flush out quickly, but in most cases the sources of contamination are relatively permanent. The major drinking water source throughout the largely rural karst area is groundwater. The Department for Natural Resources and Environmental Protection's Division of Water began assessing groundwater quality problems under the auspices of Section 208 of the Clean Water Act, and learned that one of the major causes of groundwater pollution in the state is improperly designed septic tanks and seepage pits. Other causes are sediment, agrichemicals, septic tank loadings, surface mining, oil and gas production, brine disposal, construction activity, and spills. Principal needs of the Division include quality research data for each aquifer, more trained personnel for groundwater management, and regulation for groundwater monitoring, well construction, and subsurface disposal. GROUND WATER IN THE OHIO RIVER BASIN PORTION OF MARYLAND: PROBLEMS AND NEEDS,
Maryland Dept. of Natural Resources, Annapolis.
E. C. Rebuck.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. P 22-26.

Descriptors: *Surface-groundwater relations, *Groundwater management, Federal jurisdiction, *Administrative regulations, State jurisdiction, *Aquifer management, Administrative agencies, Groundwater depletion, Groundwater level, Acid mine drainage, Mine acids, Hydrologic models, *Ohio River basin, *Maryland, Garrett County.

The Ohio River Basin portion of Maryland lies wholly within Garrett County, an area rich in minerals where the primary surface water resources are the Youghiogheny River and the Casselman River. While the two rivers have been shown to have good water quality, smaller tributaries do not meet stream water quality standards due to acid mine drainage pollution. Springs are important sources of domestic and municipal ground water supplies in the county. Hydraulic connection between the streams and ground waters is poorly understood. The U. S. Geological survey is pursuing a modeling study in the Casselman River Basin which will attempt to correlate base stream flow with ground water levels. On the state level, programs for ground water protection are administered by the Department of Water Resources and the Department of Health and Mental Hygiene. On the federal level, the Environmental Protection Agency is involved with activities covered by the Resources Conservation and Recovery Act of 1976, the Underground Injection Control program in the Safe Drinking Water Act (SDWA), and the sole source aquifer protection program of SDWA. Perhaps the most important technical need is the updating of the 1954 water resources reported by the USGS. Another need is better coordination among federal and state environmental regulatory efforts, especially now in times of tight economic conditions where environmental control budgets may be cut at both federal and state levels. (Garrison-Omniplan)
W82-01054

GROUNDWATER PROBLEMS AND NEEDS IN NEW YORK,
New York State Dept. of Environmental Conservation, Albany.
A. C. Tedrow.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 27-29.

Descriptors: *Groundwater management, *Drinking water, *Groundwater availability, *Groundwater pollution, Research priorities, Administrative agencies, *Administrative regulations, Waste disposal, Water management, Reclaimed water, State jurisdiction, Local governments, Brine disposal, *New York.

A Groundwater Task Force convened in 1979 by the New York State Department of Environmental Conservation examined in-house groundwater management programs. Among its conclusions were that: (1) not enough is known about the resource itself, specifically with regard to current quality levels; (2) monitoring of changes in groundwater quality is adequate, so that violations of groundwater quality standards are often not discovered until they have created a problem; (3) oil and gas and mined land reclamation progrems in the Department are understaffed, so that groundwater impacts of the activities they regulate receive insufficient attention; (4) the Department should support local efforts in managing groundwater; (5) research is needed on groundwater reclamation and renovation; (6) Department personnel must be trained to be more sensitive to groundwater concerns, and technical staff must be developed to deal with groundwater questions; (7) a

classification system should be considered that includes fresh groundwater uses other than drinking water; (8) the possibility of utilizing wasteload allocations for discharges to groundwater should be explained; and additional groundwater management activities are required in the upstate area. Under the 208 program, projects are underway to investigate the technical, institutional, and financial aspects of changes in groundwater management, to develop better controls over underground storage of hazardous materials, and to investigate pesticide and fertilizer application practices in relation to groundwater quality. In the Ohio River Basin area, there are problems with high nitrate levels and brine disposal. (Garrison-Omniplan)
W82-01055

GROUNDWATER PROBLEMS IN NORTH CAROLINA,
North Carolina Dept. of Natural Resources and Community Development, Raleigh.
P. F. Nelson.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 30-31.

Descriptors: *Groundwater management, Public opinion, *Deep wells, *Groundwater availability, *Legislation, State jurisdiction, Attitudes, Administrative agencies, Long-term planning, Multiobjective planning, Surface-groundwater relations, Boreholes, *North Carolina.

Planning for developing groundwater resources is not currently a very sophisticated process in North Carolina. Although much work has been done in the past to describe the hydrologic characteristics of the Coastal Plain aquifers, very little is known about the development potential in the Piedmont and mountain regions. Lack of knowledge of the availability of the resource, and widespread misunderstanding of groundwater on the part of the public, has resulted in its under-utilization in many areas. A hesitancy to drill deep wells prevails, although there is mounting evidence that contrary to public opinion, 600- and 700-foot wells are often extremely more productive than the borehole drilled to 175 feet. North Carolina's needs with respect to groundwater protection and wise management are: (1) recognition of the need for a comprehensive groundwater program; (2) prompt statewide implementation of the Groundwater Classification and Quality Standards; (3) an effective Water Well Contractors Licensing Board to examine and approve operators as well as contractors; (4) improved groundwater management legislation, as the existing Act is cumbersome to employ and has the potential of creating a 'patchwork quilt' of water management areas. The need to become more involved in groundwater research in the fractured rock terrain is becoming more and more critical as Piedmont cities exhaust their available surface water resource. (Garrison-Omniplan)
W82-01056

OHIO'S GROUND WATER RESOURCES AND PROBLEM AREAS,
Ohio Environmental Protection Agency, Columbus. Groundwater Div.
R. B. Stein.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 32-33.

Descriptors: *Groundwater availability, *Groundwater management, *Groundwater pollution, Water pollution, Wells, Waste disposal, Poisons, Multiobjective planning, Water use, Competing use, Long-term planning, Legislation, State jurisdiction, Administrative regulations, Public policy, *Ohio.

Ohio's ground water reserves, while abundant, are unequally distributed. Ground water quantity problems can be attributed to cyclic drought conditions. Conflicts between groundwater users have been noted in a number of areas and are usually the result of well interference between two or more large users or one large user affecting water levels in nearby shallow wells. For the most part, the problems have been resolved voluntarily by adjusting pumping rates and schedules, or by developing additional production wells beyond the area of pumping interference. Ohio, being a densely populated and highly industrial state, generates large volumes of both liquid and solid wastes. Based upon groundwater complaint investigations conducted by the Ohio EPA over the past eight years, the most prevalent ground water contamination problems are from domestic on-lot sources affecting private individual wells. Contamination has most often been the direct result of poor well construction and maintenance, or improper well abandonment. Other leading causes of contamination have been salt water effects related to oil and gas production or improperly plugged oil wells, and coal leaching effects. Ohio's major concerns in ground water program planning are to define agency roles and coordinaton, determine staff capability and training, develop public education and awareness, and increase data collection and regulatory practices. PENNSYLVANIA GROUND WATER PROBLEMS AND NEEDS,
Pennsylvania Dept. of Environmental Resources, Harrisburg.
R. T. Weston.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 34-40.

Descriptors: *Groundwater management, *Long-term planning, *Groundwater availability, *Groundwater pollution, Water pollution, Coal mining, Data collection, Administrative regulation, *Legislation, Public policy, State jurisdiction, Drinking water, Multiobjective planning, *Pennsylvania.

Over half of Pennsylvania' public water supply systems obtain all their water from ground water aquifers, and another 13 percent meet part of their demands with ground water. Potentials for conflict among competing water users are growing. As water needs grow, ground water will fill an increasing part of the demand. Ground water planning is hampered by limited use data and incomplete hydrogeologic information, but several problem areas have been identified. Some Triassic basins are extremely susceptible to drought, and recharge slowly after heavy withdrawal. Interference between public and private withdrawals, such as overlapping cones of depression between neighboring wells or pumping operations, is another problem area. Mining operations frequently dewater large areas. In water quality preservation, problem areas include malfunctioning on-lot sewage systems, inadequately designed or operated waste disposal facilities, leaking storage tanks and pipelines, transportation accidents, poorly operated agricultural activities, roadways and parking lots where runoff infiltrates the ground, past or current mining, and oil and gas recovery operations. Acid drainage from bituminous coal mining is a problem in some areas. Pennsylvania has no comprehensive legal or institutional approach to water allocation. Common law often operates contrary to hydrologic fact, treating interrelated ground and surface water resources under separate and inconsistent rules. State authority to regulate water allocation is extremely narrow. A reform of State water management policy is proposed, and fourteen major goals are outlined. (Mantius-Omniplan)
W82-01058

GROUND WATER PROBLEMS VIRGINIA PORTION OHIO RIVER BASIN,
Virginia State Water Control Board, Richmond.
A. H. Giles.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 42-62. 16 Fig.

Descriptors: *Groundwater management, River basins, Geohydrology, *Groundwater pollution, Water pollution, *State jurisdiction, Rivers, Groundwater availability, Underground stream, Coal mining, Aquifers, Aquifer management, Aquifer characteristics, *Ohio River basin, *Virginia.

The area drained by the headwaters of several Ohio River tributaries in southwestern Virginia covers three geologic/physiological provinces with somewhat rugged terrain, some broad valleys and moderate climate and rainfall. Generally ground water is abundant and of good quality but hard in the limestone aquifers of the Valley and Ridge Province. In the flood plain alluvium of the Valley and Ridge and Piedmont it is moderately abundant, and in the Piedmont, Valley and Ridge and cumberland Plateau's soils and rocks other than limestone it is of relatively small yield. Faulting and fraction enhances production. Some surface pollution has been reported in limestone aquifers in the Valley and Ridge, which are especially susceptible to pollution. In the Cumberland Plateau, ground water pollution and loss of supply potentially are associated with natural gas and coal extraction activities, and most deeper aquifers are naturally salty. Metal mining elsewhere threatens ground water quality. The most serious pollution problems throughout the area are from petroleum product storage tank leaks and spills, waste facilities, and local urbanization. Effects of salt water and gas invasion have been observed in the Cumberland Plateau. The State Water Control Board has been effective in local pollution response, waste facility evaluation and well site evaluation. For most of the area, ground water information is minimal, but in some areas, county-wide ground water reports are being published. (Garrison-Omniplan)
W82-01059

GROUND WATER PROBLEMS IN WEST VIRGINIA,
West Virginia Dept. of Natural Resources, Charleston. Div. of Water Resources.
J. Northeimer.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 63-75. 1 Fig, 2 Tab, 2 Append.

Descriptors: *Groundwater management, *Groundwater pollution, Water pollution, State jurisdiction, *Administrative regulations, Public policy, Drinking water, *Legislation, Federal jurisdiction, Groundwater availability, Long-term planning, Multiobjective planning, *West Virginia.

Approximately 53 percent of the population of West Virginia obtains drinking water from ground water sources; however, historically there has been very little effort devoted to its protection and maintenance. Although the state ground water protection program is still in the developmental stage, participation in the various federal programs addressing ground water is providing the necessary resources for an effective regulatory framework. As the state assumes authorization for implementing these programs, the proper management of ground water will become a reality. Major limiting factors in the development of an adequate ground water management program at the state level are poorly developed control programs authorized under state statute, no central or coordinating regulatory approach or strategy, lack of initiative under the 106 program, no comprehensive monitoring network, no regulatory control over ground water development, and lack of adequate state-level funding. Statutory changes are currently being pursued at the state level to allow state implementation of federal programs which address ground water protection and maintenance, such as the Hazardous Waste Management Program under the Resource Conservation and Recovery Act, and the Underground Injection Control Program under the Safe Drinking Water Act. MATHEMATICAL MODELING TECHNIQUES FOR GROUNDWATER MANAGEMENT,
Prickett (Thomas A.) and Associates, Urbana, IL.
T. A. Prickett.
In: Proceedings and Recommendations of the Workshop on Groundwater Problems in the Ohio River Basin, Cincinnati, April 28-29, 1981. Purdue University, Water Resources Research Center, West Lafayette, IN. p 97-104. 170 Ref.

Descriptors: *Mathematical models, *Groundwater management, *Data collections, *Model studies, Hydrologic models, Hydrologic data collections, Digital computers, Computers, Multiobjective planning, Long-term planning, Decision making, Data acquisition, Numerical analysis.

Mathematical modeling has served an important role in groundwater management. Mathematical groundwater models provide a broad range of techniques for analysis of groundwater problems, including not only sophisticated numerical techniques solved with digital computers but analytical formulas worked out with desk calculators, type curves, and a table of well functions. Despite the dominance of numerical model development in the 1970s, new analytical formulas continue to be found in the recent literature. Numerical and analytical models developed to date are impressive. Also, computational devices are readily available in all ranges of price and capability. However, progress is needed that involves (1) making present and future models more useful by adequately documenting codes and procedures for their application (2) developing a large group of models aimed at solving problems in the range of simple to moderate complexity; and (3) developing models and techniques that produce results that managers can understand. Based on a survey on modeling inadequacies conducted by Bachmat (1978), the major problem with existing groundwater models was that few are documented sufficiently to be useful. The development of more simple and moderately complex models should also be keyed to quick evaluation of many alternatives. A group of educational materials is needed to help managers understand the purposes, capabilities, and results of mathematical models. (Garrison-Omniplan)

4C. Effects On Water Of Man's Non-Water Activities

SESTON DYNAMICS IN SOUTHERN APPALACHIAN STREAMS: EFFECTS OF CLEAR-CUTTING,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
M. E. Gurtz, J. R. Webster, and J. B. Wallace.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 4, p 624-631, April, 1980. 7 Fig, 4 Tab, 28 Ref.

Descriptors: *Clear-cutting, *Logging, *Seston, *Forest watersheds, Forest management, Road construction, *Streams, Suspended sediments, Suspended solids, Sediment transport, Seasonal variation, Storm runoff, Litter, Organic matter, Particle size, Particulate matter, Southern Appalachian streams.

Two second order streams of the southern Appalachian Mountains where heavy logging activities are practiced were studied for suspended particulate matter (seston) from July 1977 to July 1978. In the stream, which drains an undisturbed hardwood forest watershed, seston levels varied with storm flows and were lowest during winter high flows. In this stream, the majority of the organic and inorganic particles were less than 105 microns in diameter. In the stream draining a forest watershed that was clearcut in 1977, increased levels of both organic and inorganic seston were found. Most of the inorganic seston of this stream was made up of particles greater than 235 microns in diameter. These increases were attributed to sediments deposited during the building of logging roads and debris entering the stream during logging activities. The rate of stream recovery will probably depend on the rate of recovery of the surrounding terrain. (Geiger-FRC)

4D. Watershed Protection

SUBMERSIBLE PUMPS HELP QUELL DAMAGE FROM MOUNT ST. HELENS MUDFLOW.
Public Works, Vol 112, No 7, p 62-64, July, 1981. 3 Fig.

Descriptors: *Damage, *Flooding, *Volcanoes, *Submersible pumps, Dredging, *Mt. St. Helens, *Mudflows, Disasters, Pumps, Wastewater treatment, Water treatment facilities, *Castle Rock, Washington, Storm water.

The eruption of Mount St. Helens caused damage to the water supply and wastewater treatment works in the town of Castle Rock, 40 miles from the volcano at the confluence of the Cowlitz and Toutle Rivers. The water supply intake was plugged with ash and debris, as were all sewage and stormwater discharge outfalls. Piping was rearranged to pump the effluent over the levee into the river. Submersible pumps were used to drain the equipment and the land behind the dikes and to pump storm water from a collection point and from a street manhole. Submersible pumps were also used to return water from dredged silt piles to the river. This pump arrangement will help protect the town from serious flooding. (Cassar-FRC)

COORDINATED EFFORT STEMS SEDIMENT AND EROSION,
Anne Arundel County Dept. of Public Works, Annapolis, MD.
D. L. Kaiser.
Public Works, Vol 112, No 7, p 54-55. July, 1981. 3 Fig.

Descriptors: *Soil conservation, *Erosion control, *Sedimentation, Conservation, *Anne Arundel County, *Maryland, Regulations, Legal aspects, Inspection, Chesapeake Bay, Soil stabilization, Permits, Grading.

Soil conservation policies are carried out in Anne Arundel County, Maryland, by the Department of Inspection and Permits, the Soil Conservation District, and the Department of Public Works. Prior to construction, a grading permit must be obtained and all plans approved. A bond or similar security is required for projects disturbing more than 15,000 sq ft of surface area. Inspections are made on site, and over 95% of violations are corrected before any notice needs to be issued. However, the mandated program review of the conservation program in 1974 and 1978 showed some inadequacies. This resulted in guidelines suggesting greater interagency communications, a new procedures manual, stricter enforcement of sediment control, and preconstruction conferences. More recently, stabilization for projects lasting over 45 days has been required. (Cassar-FRC)

COSTS OF ALTERNATIVE POLICIES FOR CONTROLLING AGRICULTURAL SOIL LOSS AND ASSOCIATED STREAM SEDIMENTATION,
Idaho Univ., Moscow. Dept. of Agricultural Economics.
D. J. Walker, and J. F. Timmons.
Journal of Soil and Water Conservation, Vol 35, No 3, p 177-183, July/August, 1980. 1 Fig, 5 Tab, 20 Ref.

Descriptors: *Farm management, *Soil conservation, *Sedimentation, *Erosion control, Soil erosion, Nishnabotna River, Iowa, Regulations, Cost-benefit analysis, Agricultural watersheds, Taxes, Land use, Economic aspects, Subsidies.

Soil erosion and sediment discharge reduction programs in agricultural land (study area Nishnabotna River basin, Iowa) were evaluated by linear programming. The most cost-effective policy among the 141 individuals solutions was the dual ban on fall plowing and straight row cultivation on slopes. Several strategies were effective in reducing soil losses by 50%--a ban on fall plowing, a soil loss tax of 10-20 cents per ton, and a subsidy for minimum tillage. These three alternatives entailed income penalties of 2-3%. More restrictive policies were capable of reducing soil loss up to 90%--a dual ban on fall plowing and straight row cultivation on slopes, an annual soil loss limit of 5 tons per acre, and a soil loss tax of $0.50-1.50 per ton. Income penalties on these schemes were less than 14%. (Cassar-FRC)

TRACTIVE FORCE DESIGN OF VEGETATED CHANNELS,
Science and Education Administration, Stillwater, OK. Water Conservation Structures Lab.
D. M. Temple.
Transactions of the ASAE, Vol 23, No 4, p 884-890, July/August, 1980. 2 Fig, 4 Tab, 12 Ref.

Descriptors: *Tractive forces, *Vegetation effects, *Channel flow, Mathematical studies, Design criteria, Turbulent flow, Flow resistance, Open channels, *Erosion control, Mathematical models.

Previous research designed to evaluate the value of a vegetal channel lining as an erosion control measure has established a relatively large data base for use in the development of semi-empirical design procedures. This report updates these design procedures by presenting a method for the application of tractive force principles to the design of vegetated channels. The allowable velocity approach currently used is related not only to soil properties, but also to the vegetal and geometric properties of the channel, requiring tabulation of each possible combination of channel slope, soil, and vegetal cover through separate consideration of the properties of soil and of vegetation. The proposed tractive force design procedure substantially simplified the investigation and tabulation of critical or allowable conditions by permitting separate consideration of the properties of soil and those of the vegetation. The protective value of vegetal channel lining is considered to be derived from two related interactions of the vegetation with the flow field: the generation of turbulent eddies at a significant distance from the soil boundary, creating an increase in flow resistance, and a change in the structure of the turbulent eddies in immediate proximity to the boundary. Two indices believed to relate directly to these interactions are used to classify the vegetation. Guidelines for the selection of these indices according to type and quality of cover are presented. Existing flow resistance curves are put into equational form as a single curve family. The design procedure is directly adaptable to programmed calculation, allowing the incorporation of optimization routines at little additional expense. (Carroll-FRC)

5A. Identification Of Pollutants

GAS CHROMATOGRAPHIC DETERMINATION OF TRIALKYL/ARYL PHOSPHATES IN DRINKING WATER, FOLLOWING ISOLATION USING MACRORETICULAR RESIN,
Health and Welfare Canada, Ottawa (Ontario). Monitoring and Criteria Div.
G. L. LeBel, D. T. Williams, and F. M. Benoit.
Journal of the Association of Official Analytical Chemists, Vol 64, No 4, p 991-998, July, 1981. 4 Fig, 5 Tab, 12 Ref.

Descriptors: *Ion exchange, *Organophosphorus compounds, *Water analysis, Phosphates, Pesticides, Drinking water, Gas chromatography, Phosphorus compounds, *Pollutant identification.

An XAD-2 screening method developed for organophosphorus pesticides was applied to the determination of trialkyl and triaryl phosphates in drinking water at the ng per liter level. Recovery studies at levels of 1, 10, and 100 ng per liter were carried out by fortification onto XAD-2 resin and by direct on-stream fortification of drinking water. Recoveries for several phosphates using direct fortification were as follows: trialkyl, 19.9-28.9%; tributyl, 88.2-101.2%; tris(2-chloroethyl), 82.9-95.5%; tri(2-ethylhexyl), 61.7-78.8%; tributoxyethyl, 104.5-125.6%; triphenyl, 95.0-107.4%; and tricresyl, 95.0-98.1%. Recoveries by continuous fortification were on the same order, with some exceptions. Drinking water samples from 6 Ontario water treatment plants contained several trialkyl and triaryl phosphates at 0.2 to 75 mg per liter levels, uncorrected for incomplete recoveries. (Cassar-FRC)

THIN LAYER CHROMATOGRAPHIC AND ATOMIC ABSORPTION SPECTROPHOTOMETRIC DETERMINATION OF METHYL MERCURY,
California Univ., Los Angeles. School of Public Health.
L. W. Margler, and R. A. Mah.
Journal of the Association of Official Analytical Chemists, Vol 64, No 4, p 1017-1020, July, 1981. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Methylmercury, Mercury compounds, *Pollutant identification, Thin layer chromatography, Atomic absorption spectrophotometry, Sludge, Fish.

Methyl mercury was determined by a combination of thin layer chromatography and atomic absorption spectrophotometry at 253.7 nm. The samples were first distilled with hydrochloric acid and copper sulfate and extracted twice with dithizone-chloroform, followed by chloroform. Dehydration and concentration preceded the chromatography procedure. Samples of tuna, trout, and anaerobically digested sewage sludge were analyzed; methyl mercury contents were 0.056 micrograms per g, 5.26 micrograms per g, and 0.012 micrograms per ml, respectively. Spiking showed that 90% of the methyl mercury was recovered from tuna and 73% from sewage sludge. The method was sensitive to 0.7 ng in the total Hg determination and 0.009 micrograms Hg per g in 100 g samples. (Cassar-FRC)

ENVIRONMENTAL VIROLOGY AND ITS PROBLEMS,
Severn-Trent Water Authority (England).
R. Morris, and W. M. Waite.
Journal of the Institution of Water Engineers and Scientists, Vol 35, No 3, p 232-244, May, 1981. 9 Ref.

Descriptors: *Viruses, *Water supply, *Public health, Culturing techniques, Potable water, Drinking water, Pollutant identification, Enteroviruses, Diseases, Microbiological studies, Water treatment, Severn-Trent Water Authority, *Great Britain.

Virus assays of waters in the Severn-Trent Water Authority jurisdiction showed that 135 (49%) of 276 surface water samples were positive, the highest level being detected being 337 pfu per liter from the River Tame. Heavily polluted rivers were 88% positive, and stored river water samples were 21% positive. Virus was present in 55% of 132 wastewater effluent samples: the highest recovery value was 5800 pfu per liter. A monkey kidney cell line, designated BGM, was the most suitable cell line tested for virus detection. The suspended cell technique gave higher recoveries than tube culture or the monolayer technique. No direct correlation was found between numbers of viruses in water and any of the bacterial indicator organisms or coliphages. Although there have been no reports of viral infections transmitted through public water supplies in the United Kingdom for many years, the Virology Unit has been established at the water authority to monitor drinking water, abstracted surface waters, and waste water effluents, and to develop more efficient and sensitive techniques for isolating and enumerating viruses. This paper includes background information on the history, character, growth, recovery and identification techniques, classification, diseases, vaccines, and survival in the water system. R FACTORS IN COLIFORM-FECAL COLIFORM SEWAGE FLORA OF THE PRAIRIES AND NORTHWEST TERRITORIES OF CANADA,
Environmental Protection Service, Edmonton (Alberta). Microbiology Lab.
J. B. Bell, W. R. Macrae, and G. E. Elliot.
Applied and Environmental Microbiology, Vol 42, No 2, p 204-210, August, 1981. 6 Tab, 23 Ref.

Descriptors: *Coliforms, *Drugs, *Sewage bacteria, Bacteria, Escherichia coli, Public health, Canada, Raw water, Treated water.

The comparative antibiotic resistance and R factors were assessed in the coliform and fecal coliform populations found in raw and treated sewage. Results showed that 8.91% of the total coliform and 10.80% of the fecal coliform populations carried R factors. The following numbers of combinations of R determinants were found: 39 in Escherichia coli, 6 in Citrobacter, 20 in Enterobacter, 10 in Klebsiella, and 11 in Aeromonas. Seven was the maximum number of R determinants transferable simultaneously, and organisms with R factors containing determinants for chloramphenicol ususally contained determinants for ampicillin. From 2 to 4% of the coliforms and fecal coliforms were resistant to chloramphenicol, and from 17 to 30% of the populations were resistant to three or more antibiotics. Final effluent discharges to the environment contained R factor carrying coliform populations of 3.1 times 10 to the 4th power/100 ml and fecal populations of 5.8 times 10 to the 2nd power/100 ml. The maximum removal of R positive bacteria from sewage before its discharge into the environment is desirable, as this may be a factor in the reduced effectiveness of antibiotics. (Small-FRC)

MONITORING TRACE AMOUNTS OF CADMIUM IN NATURAL WATERS,
Brandon Univ. (Manitoba). Dept. of Chemistry.
K. Srikameswaran, H. D. Gesser, and M. Venkateswaran.
Journal of Environmental Science and Health, Part A, Vol 15, No 4, p 323-337, 1980. 2 Fig, 4 Tab, 5 Ref.

Descriptors: *Cadmium, *Trace metals, Natural waters, Water analysis, *Pollutant identification, Chelating agents, Heavy metals, Monitoring.

Cadmium may be determined semiquantitatively in trace amounts in water by using 1-(2-pyridylazo-2) naphthol loaded polyester foams. This chemical is a good complexing agent in the pH 7-8 range, forming a visible orange complex with Cd. The apparatus is operated by squeezing a piece of prepared foam with a piston in a tank of water. Cd concentrations of 3.7, 7.9, 18.6 and 55.9 micrograms per liter were used to determine the amount of Cd extracted by the chemically treated foams in a given number of squeezes (250-1500). Results varied from 5 micrograms Cd from water at 3.7 micrograms per liter concentration and 250 squeezes to 200 micrograms Cd from water at 55.9 micrograms per liter concentration and 1500 squeezes. A plot of Cd extracted per squeeze vs. number of squeezes produced a straight line for each concentration tested. The concentration of Cd in unknown waters may be estimated from a graph plotting Cd concentration against micrograms Cd extracted per squeeze. Other heavy metal ions (Zn, Pb, Cu, and Fe at 100 microgram per liter levels) had no significant effect on the results. (Cassar-FRC)

INDUSTRIAL EFFLUENT MONITORING INCORPORATING A RECENT AUTOMATED FISH BIOMONITORING SYSTEM,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Center for Environmental Studies.
D. Gruber, and J. Cairns, Jr.
Water, Air, and Soil Pollution, Vol 15, No 4, p 471-481, May, 1981. 4 Fig, 38 Ref.

Descriptors: *Bioindicators, *Effluents, *Industrial wastes, *Pollutant identification, Fish, Fishkill, Water quality control, Monitoring, *Munitions wastes, Respiration, Water pollution effects, Toxicity, Ammunition plant, Radford, Virginia.

A series of experiments is described which implies that the present concept of automated and continuous biological monitoring is capable of detecting an industrial spill from an ammunition manufacturing plant. The sampling facility is located on site at a US Army Ammunition Plant in Radford, Virginia. Bluegill sunfish, Lepomis macrochirus Raf., served as sensors. Each fish is monitored within individual 6 liter monitor tanks. Twenty-four similar monitor tanks are housed within a compartmentalized module. A minicomputer system converts analog signals into digital information and uses a modified peak-picking program to quantify the frequency of ventilation for each fish over time. Chemical and physical parameters of the effluent are also continuously monitored and interfaced with the computer system. The alarm system consists of a display panel with lights and a bell system within the computer's keyboard. In a 48 hr static bioassay test, the concentration of roll powder effluent which killed half the fish was 25%. However, during a subsequent exposure, all fish survived in 100% effluent. All exposed animals significantly altered their ventilatory behavior within 30 minutes after the initial introduction of the effluent. All which survived had ventilatory rates return to normal within several hours after the effluent exposure ceased. Nitroglycerin was detected at 1.2 ppm in monitor tanks in a water sample taken during a specific time period. Concentrations of DEP and lead were also determined. (Baker-FRC)

A STUDY OF SAMPLES OF WELL WATER COLLECTED FROM SELECTED AREAS IN CALIFORNIA TO DETERMINE THE PRESENCE OF DBCP AND CERTAIN OTHER PESTICIDE RESIDUES,
California Dept. of Food and Agriculture, Sacramento.
S. A. Peoples, K. T. Maddy, W. Cusick, T. Jackson, and C. Cooper.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 4, p 611-618, 1980. 3 Tab.

Descriptors: *Agriculture, *Agricultural chemicals, *Organic compounds, *Pesticide residues, *Water sampling, *Irrigation, Carcinogens, Wells, *Well water, Water pollution, Toxicity, Chemical analysis, Crop production, Well data, Soil contamination, Soil analysis.

A survey of possible soil and well-water contamination with DBCP and other pesticide residues

was conducted in selected California counties in 1979. Liquid 1,2-dibromo-3-chloropropane was used as a soil nematicide in California until 1977, when it was banned as a potential carcinogen. In Yolo County all well-water samples were negative. In Ventura and Riverside County wells, samples were also negative. Samples from the east of San Joaquin Valley exhibited contamination in 50% of the wells, primarily those less than 100 feet deep. The route by which DBCP contaminates water supplies is not known. (Titus-FRC)
W82-00532

DETERMINATION OF TERBUTRYN AND ITS DEGRADATION PRODUCTS IN WATER, SEDIMENTS, AQUATIC PLANTS, AND FISH,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
D. C. G. Muir.
Journal of Agricultural and Food Chemistry, Vol 28, No 4, p 714-719, July/August, 1980. 4 Fig, 4 Tab, 18 Ref.

Descriptors: *Chemical analysis, *Water, *Terbutryn, Chromatography, Agricultural chemicals, *Herbicides, Ponds, Aquatic plants, Degradation, Farm ponds.

A method for the determination of terbutryn and several of its degradation products, N-deethylated terbutryn (DET), hydroxyterbutryn (HT), N-deethylated hydroxyterbutryn (DEHT), 2-(tert-butylamino)-4-(ethylamino)-s-triazine (EBT), and 2-(tert-butylamino)-4-amino-s-triazine (ABT), is reported. Water samples were extracted with dichloromethane. Sediment, aquatic plant, and fish tissue samples were extracted with aqueous acetonitrile. The hydroxytriazines were isolated by chromatography on a cation-exchange resin and cleanup on alumina and by high-pressure liquid chromatography. Recoveries of terbutryn, DET, HT, DEHT, ABT, and EBT from water (0.5 - 50 micrograms/liter) ranged from 76 to 120%. Terbutryn and DET recoveries from sediment, plants, and fish tissues (0.05 - 0.9 micrograms/gram) ranged from 74 to 106%. HT and DEHT recoveries from sediment, plant material, and fish tissue (0.1 to 1.23 micrograms/gram) ranged from 62 to 124%. (Baker-FRC)

SEARCH FOR LINURON RESIDUES IN TRIBUTARIES OF THE CHESAPEAKE BAY,
Du Pont de Nemours (E. I.) and Co., Wilmington, DE. Dept. of Biochemicals.
E. W. Zahnow, and J. D. Riggleman.
Journal of Agricultural and Food Chemistry, Vol 28, No 5, p 974-978, September/October, 1980. 6 Fig, 4 Tab, 14 Ref.

Descriptors: *Agricultural chemicals, *Aquatic plants, Bays, *Herbicides, *Chesapeake Bay, Tributaries, *Linuron, Leaching.

The possible transfer of linuron from farm fields into the Chesapeake Bay was examined using extraction with acetonitrile followed by liquid chromatography. In the sampling area the principal usage of linuron is on soybeans at 0.55 kg/ha. Treatment is made between mid-May and early July. The first sampling followed the first major rain at the end of the treatment season. The second sample was taken 2 months later. Mud, soil and water samples were taken. The analysis of mud and water samples taken during the two successive summers showed no evidence of linuron accumulation. Samples from drainage basins receiving up to 45,000 kg of linuron annually showed no linuron residue, i.e., less than 10 ppbw in the mud and less than 0.2 ppb, w/v in the water. On this basis it was concluded that linuron usage on fields bordering Chesapeake Bay waters and its tributaries is not a contributing factor to the recent declines in the abundance of aquatic plants in the area. (Baker-FRC)
W82-00569

EVALUATION OF VARIOUS SOIL WATER SAMPLERS FOR VIROLOGICAL SAMPLING,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
D-S. Wang, J. C. Lance, and C. P. Gerba.
Applied and Environmental Microbiology, Vol 39, No 3, p 662-664, March, 1980. 2 Fig, 1 Tab, 12 Ref.

Descriptors: *Sampling, *Viruses, Water quality, Drinking water, Wastewater, Effluent, *Soil water, Water analysis.

Various types of ceramic soil water samplers were evaluated for virus sampling. Both tap water and sewage effluent were used in the study. Secondary sewage was collected from the effluent of an activated sludge treatment plant before chlorination. The tap water was dechlorinated with sodium thiosulfate before use. Poliovirus 1 (strain LSc), echovirus 1 (strain V239), bacteriophage T2, and bacteriophage MS-2 were added to water samples for the experiments. Before sampling, 500 ml of water was seeded with virus to obtain a concentration of 100,000-1,000,000 plaque-forming units per ml. The percentage recoveries of viruses in water samples after passage through the three samplers was determined. To test the possibility that particulate matter present in the water sample could influence the passage of virus through the samplers, the recovery of virus from both unfiltered and filtered water samples was compared. In general, no significant difference in virus recovery was observed between unfiltered and filtered samples. Soil water samples obtained from both the ceramic cup soil water sampler and the porous ceramic tube exhibited low recoveries of poliovirus and bacteriophage T2. Recoveries of MS-2 and echovirus 1 were substantially higher. The ceramic sampler constructed in the laboratory performing the investigation was consistently superior to the two commercially available soil water samplers tested. (Baker-FRC)
W82-00572

SIMULTANEOUS CONCENTRATION OF SALMONELLA AND ENTEROVIRUS FROM SURFACE WATER BY USING MICRO-FIBER GLASS FILTERS,
Nancy-1 Univ. (France). Lab. d'Hygiene et de Recherche de la Sante Publique.
D. Rolland, and J. C. Block.
Applied and Environmental Microbiology, Vol 39, No 3, p 659-661, March, 1980. 2 Tab, 6 Ref.

Descriptors: *Bacteria, *Surface water, *Salmonella, *Enteroviruses, Filters, Viruses, Monitoring, Recreation facilities, Water quality, Bacterial analysis.

Surface waters were sampled at weekly intervals in January 1979 from the Meurthe River, 8 km south from the city of Nancy, France. Salmonella testing was conducted using a micro-fiber glass filter of 8 micrometers porosity, at pH 3.5. Simultaneous concentrations of Salmonella and enterovirus were determined. Quantitative analysis indicated that Salmonella and viruses are effectively retained or adsorbed or both at pH 3.5 on micro-fiber glass filters. The viral concentrations ranged from 0 to 2.3 MPNCU/liter and the Salmonella concentrations ranged from 1 to 80 bacteria/liter. For Salmonella, as for viruses, a concentration step was required. The water tested was of poor quality due to the presence of a wastewater treatment plant output of the city located 8 km upstream. It was concluded that adsorption at pH 3.5 to microfiber glass filters offers a rapid, effective, quantitative, and relatively inexpensive method for simultaneous concentration of Salmonella and enterovirus. Recreational water quality can then be monitored for two parameters from a single concentration. (Baker-FRC)

RELATIONSHIPS BETWEEN ENVIRONMENTAL FACTORS, BACTERIAL INDICATORS, AND THE OCCURRENCE OF ENTERIC VIRUSES IN ESTUARINE SEDIMENTS,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
R. L. LaBelle, C. P. Gerba, S. M. Goyal, J. L. Melnick, and I. Cech.
Applied and Environmental Microbiology, Vol 39, No 3, p 588-596, March, 1980. 3 Fig, 3 Tab, 41 Ref.

Descriptors: *Estuarine environment, *Viruses, Bacteria, *Sediments, Enteric bacteria, Enteroviruses, Indicators, Bioindicators, Recreation, Recreation facilities, Public health, Epidemiology, Shellfish farming.

The occurrence of enteric viruses in estuarine sediments was examined in efforts to find a possible relationship between the presence of viruses in seawater or sediment or both and various biological and physiochemical characteristics of the environment. Sediment was found to contain greater numbers of viruses than overlying seawater on a volume basis. Several types of enteroviruses were isolated, including coxsackievirus types A16, B1, and B5, echovirus type 1, and poliovirus type 2. On several occasions, viruses were isolated from sediments when overlying waters met bacteriological water quality standards for recreational use. Only one significant association was noted in the statistical analysis of a possible relationship between viruses in seawater or in sediment and other variables. This association indicated that the number of viruses in sediment was positively correlated with the number of fecal coliforms in the sediment. No other statistically significant associations were found. Bacterial indicators and viruses in the overlying waters did not appear to be correlated. The evaluation of the presence of bacteria and viruses in sediment may give additional insight into long-term water quality conditions. It is noted that indicator bacteria in water are not reflective of the concentration of enteric viruses in marine waters. (Baker-FRC)

EFFECTS OF WASTEWATER SLUDGE AND ITS DETERGENTS ON THE STABILITY OF ROTAVIRUS,
Sandia Labs., Albuquerque, NM.
R. L. Ward, and C. S. Ashley.
Applied and Environmental Microbiology, Vol 39, No 6, p 1154-1158, June, 1980. 3 Fig, 4 Tab, 12 Ref.

Descriptors: *Sludge, *Viruses, *Detergents, Growth, Rotavirus, Wastewater, Reovirus.

A series of inactivation experiments in wastewater sludge were performed with SA-11, a rotavirus strain isolated from a vervet monkey. Wastewater sludge reduced the heat needed to inactivate rotavirus SA-11, and ionic detergents were identified as the sludge components which were responsible for this effect. This is similar to an effect that had been found earlier with reovirus. The quantitative effects of individual ionic detergents on rotavirus and reovirus were very different, and rotavirus was extremely sensitive to several of the detergents. However, neither virus was destabilized by nonionic detergents. On the contrary, rotavirus was stabilized by a nonionic detergent against the potent destabilizing effects of the ionic detergent sodium dodecyl sulfate. The destabilizing effects of both cationic and anionic detergents on rotavirus were greatly altered by changes in the pH of the medium. Although there may be a number of compounds in sludge that can stabilize rotavirus, nonionic detergents, which are known ingredients of sewage, were shown here to have this stabilizing effect. It is possible that removal of nonionic detergents from sludge caused the destabilizing effects of ionic detergents to be better expressed after their separation from other sludge components. (Baker-FRC)

GROWTH OF AEROMONAS HYDROPHILA AT LOW CONCENTRATIONS OF SUBSTRATES ADDED TO TAP WATER,
Netherlands Waterworks, Rijswijk. Testing and Research Inst.
D. Van der Kooij, A. Visser, and W. A. M. Hijnen.
Applied and Environmental Microbiology, Vol 39, No 6, p 1198-1204, June, 1980. 3 Fig, 4 Tab, 29 Ref.

Descriptors: *Drinking water, *Bacteria, Growth, Water pollution, *Aeromonas, Microorganisms, Bioassay, Water treatment, Water quality, Substrates, Biodegradation.

The growth of Aeromonas hydrophila at low substrate concentrations was investigated as part of an investigation on the behavior of different types of bacteria in tap water. Batch experiments were conducted using tap water supplied with low concentrations of substrates. Growth was assessed by colony count determinations. The isolate only multiplied in the used tap water after the addition of a small amount of an assimilable carbon compound. d-Glucose especially caused growth of the organism even at initial concentrations below 10 micrograms C per liter. At initial glucose concentrations below the substrate concentration value (12 micrograms C per liter), generation times and yield were nonlinear with 1/initial glucose concentrations and initial glucose concentrations respectively. The maintenance coefficient m was calculated from these observations. At initial concentrations below the substrate concentration value of starch, no growth was noted, but complete use of starch occurred in these situations after the addition of 10 micrograms of glucose-C per liter. The results of this study demonstrated that information of ecological significance may be obtained by very simple batch experiments. Moreover, the isolate studied may be used in growth experiments to assess the maximum concentration of glucose present in water, particularly tap water, initially or after various treatment stages. ISOLATION AND IDENTIFICATION OF PATHOGENIC MICROORGANISMS AT WASTEWATER-IRRIGATED FIELDS: RATIOS IN AIR AND WASTEWATER,
Hebrew Univ., Jerusalem (Israel). Environmental Health Lab.
B. Teltsch, S. Kedmi, L. Bonnet, Y. Borenzstajn-Rotem, and E. Katzenelson.
Applied and Environmental Microbiology, Vol 39, No 6, p 1183-1190, June, 1980. 1 Fig, 8 Tab, 31 Ref.

Descriptors: *Wastewater irrigation, *Pathogens, Microorganisms, Salmonella, Enteroviruses, Bacteria, Viruses, Coliforms, Poliovirus, Spray irrigation, Sprinkler irrigation.

The occurrence of Salmonella bacteria and animal enteroviruses in aerosol emissions from wastewater irrigation sites was determined by direct assay. An evaluation was made of the suitability of coliforms as indicators of airborne contaminations. Throughout this study different types of sprinklers were used, and consequently different discharge rates, particle numbers, and aerosol volumes were generated in the experimental fields. The frequency of positive Salmonella samples was 78% in the wastewater and 18% in the airborne emissions. For enteroviruses, the frequency of positive samples was 71% in the wastewater and 44% in aerosol emissions, indicating higher frequency of enteroviruses in aerosol emissions in comparison to Salmonella. The results indicate that enteroviruses and Salmonella bacteria survive in the air better than coliform bacteria. In addition it appears that the enteroviruses are more hardy than Salmonella in wastewater aerosols. Although coliforms were present in all air samples, their use as indicators of the microbial contamination of air may result in an inaccurate assessment of the true presence or survival of pathogens. DESTRUCTION BY ANAEROBIC MESOPHILIC AND THERMOPHILIC DIGESTION OF VIRUSES AND INDICATOR BACTERIA INDIGENOUS TO DOMESTIC SLUDGES,
Environmental Protection Agency, Cincinnati, OH. Office of Research and Development.
G. Berg, and D. Berman.
Applied and Environmental Microbiology, Vol 39, No 2, p 361-368, February, 1980. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Bacteria, *Sludges, *Bioindicators, Indicators, Temperature effects, Digestion, *Viruses, Water treatment facilities, Wastewater treatment.

The usefulness of fecal coliforms, total coliforms, and fecal streptococci as indicators of viruses in raw and digested sludges is demonstrated. The extent to which indicator bacteria and some viruses are destroyed by anaerobic mesophilic and thermophilic digestion of domestic wastewater sludges as these sludge stabilization processes are currently practiced is also examined. Large variations were found in the numbers of viruses occurring over narrow ranges of numbers of fecal coliforms, total coliforms, and fecal streptococci in raw sludges and in mesophilically and thermophilically digested anaerobic sludges. This finding suggests that the bacteria were poor quantitative reflectors of the numbers of the viruses detected. All three indicator bacteria were destroyed more rapidly than were the viruses by mesophilic and thermophilic digestion of the anaerobic sludges. The relative rates for the destruction of viruses, fecal coliforms, and fecal streptococci in the digested sludges were consistent over the 17 month study. Fecal coliforms were 7 to 8 times more sensitive than the viruses to mesophilic digestion and 9 to 10 times more sensitive to thermophilic digestion. Even more sensitivity was noted among the total coliforms. The rates at which fecal streptococci were destroyed by mesophilic and thermophilic digestion of anaerobic sludges approached those at which the viruses were destroyed by those processes. This suggests that rates of fecal streptococci destruction may be used as indicators for the rates at which viruses in sludges are destroyed by these processes. (Baker-FRC)

MONITORING RIVER PERIPHYTON WITH ARTIFICIAL BENTHIC SUBSTRATES,
Bowling Green State Univ., OH. Dept. of Biological Sciences.
R. L. Lowe, and W. F. Gale.
Hydrobiologia, Vol 69, No 3, p 235-244, March, 1980. 2 Fig, 4 Tab, 17 Ref.

Descriptors: *Periphyton, *Substrates, *Algal growth, Algae, Rivers, *Benthic environment, *River beds, Monitoring, Susquehanna River, Species composition, Water quality analysis, Pennsylvania.

Frosted acrylic was the most satisfactory artificial substrate for studying periphyton colonization on a river bottom. Other substrates tested at the bottom of the Susquehanna River, near Falls, Pennsylvania, were smooth glass, frosted glass, Vermont slate, and sandy slate (flagstone). Natural river stones were collected for comparison. The most abundant algae on the substrates were diatoms, with Nitzschia and navicula most often dominating. The genera Cocconeis, Synedra, Asterionella, Gomphonema, Meridion, Cymbella, Fragilaria, Stephanodiscus, Cyclotella, and Melosira were also well represented. A 1-month exposure time showed very little colonization in December through April, but from May through November, communities from 1,000 to 10,000 units per sq mm were found. The densest communities were accumulated in October. The long-term, or cumulative, substrates had the densest periphyton communities in winter, with decreasing densities in June-October. The greatest periphyton density was found on a river stone in February (21,850 units per sq mm). Any of the substrates would be satisfactory to determine the dominant genera in the periphyton. The number of genera on artificial substrates tended to be higher than the numbers on river stones. It is suggested that 1-month colonization periods are not enough; substrates should be collected after several month's submergence. (Cassar-FRC)

CATION CHROMATOGRAPHY WITH A CONDUCTIVITY DETECTOR,
Ames Lab., IA.
J. S. Fritz, D. T. Gjerde, and R. M. Becker.
Analytical Chemistry, Vol 52, No 9, p 1519-1522, August, 1980. 6 Fig, 5 Ref.

Descriptors: *Chromatography, *Cations, *Cation exchange, *Conductivity, Drinking water, Water analysis, Hardness, Ammonium, Calcium, Manganese.

A system for cation analysis which successfully separates inorganic and amine cations was developed. Using this cation chromatography system metal and ammonium cations are separated on a cation-exchange column of low capacity and are detected with a conductivity detector. There is no need for a suppressor column. Mixtures of alkali metal and ammonium ions are separated using a nitric acid eluent, while an eluent containing an ethylene-ammonium salt is used to separate magnesium, calcium, strontium, and barium ions. The procedure requires 5 to 10 min. In experiments with drinking water, the method was used to determine alkali metal ions, ammonium, magnesium(II), and calcium(II). This procedure is similar in speed and convenience to atomic spectrometry methods, and has the advantage that ammonium ions can be determined simultaneously. Cation chromatography is a promising method for water hardness analysis, as it gives both magnesium and calcium hardness. (Small-FRC)

ENUMERATION OF BACTERIOPHAGES AND HOST BACTERIA IN SEWAGE AND THE ACTIVATED-SLUDGE TREATMENT PROCESS,
Clemson Univ., SC. Dept. of Microbiology.
D. L. Ewert, and M. J. B. Paynter.
Applied and Environmental Microbiology, Vol 39, No 3, p 576-583, March, 1980. 6 Tab, 26 Ref.

Descriptors: *Bacteria, *Wastewater, Bacteriophage, Viruses, *Wastewater treatment, Water treatment facilities, Effluents, Influent water, Activated sludge, Sludge.

Enumeration was made of bacteriophage populations in an activated-sludge sewage treatment plant. A newly developed assay for quantitation of total phases, employing direct electron microscopic counts, was used in conjunction with the plaque assay. The total concentration of phages was significantly higher in reactor mixed liquor and effluent than in influent sewage, indicating a net production of phages within the reactor. Maximum total phage concentrations in the fluid phase of sewage, activated-sludge mixed liquor, and reactor effluent, were 2.2 times 10 to the seventh power, 9.5 times 10 to the seventh power, and 8.4 times 10 to the seventh power, respectively. In general, specific phage titers were lower in mixed liquor than in sewage, indicating that these hosts were not responsible for the net production of phages in the reactor. This study emphasizes the limitations of the plaque assay for ecological studies of phages, and suggests that bacteria responsible for phage production in activated-sludge mixed liquor either mirror components of the heterotrophic population, floc-producing strains, or members of other physiological groups. METAL SPECIATION. EFFECTS ON AQUATIC TOXICITY,
Illinois Inst. of Tech., Chicago. Pritzker Dept. of Environmental Engineering.
H. E. Allen, R. H. Hall, and T. D. Brisbin.
Environmental Science and Technology, Vol 14, No 4, p 441-443, April, 1980. 2 Fig, 1 Tab, 24 Ref.

Descriptors: *Aquatic life, *Metals, Metal complexes, *Chelating agents, Toxicity, Metal-finishing wastes, Industrial wastes, Heavy metals, Algae, *Algal growth, Natural waters.

The effect of chelation in aquatic environments has been investigated. Experiments were conducted to demonstrate that algal toxicity is related to the free metal ion and not to the total soluble metal concentration. A series of algal bioassays was conducted in which zinc and various chelators were added. To relate algal growth to the chemical forms of zinc present, stability constants for the reaction of each of the chelators with hydrogen, calcium, and magnesium ions, as well as with zinc ions, were required. For all cultures in which there was an increased number of algae after 5 days, the logarithm of the number of cells was plotted vs. the calculated concentration of free zinc. In addition, data were included for a series of controls in which no additional chelator was added to the media, but

in which the concentration of added zinc was varied. The results demonstrated that the toxicity of trace metals to algae is directly dependent on the concentration of free metal ion rather than the total metal concentration. This method of predicting biological toxicity could be extended to natural waters provided adequate information on organism response to and equilibrium relations for the metal are available. An understanding of the relationship of an organism's response to the specific chemical form of a toxicant in the environment rather than to its total concentration is an important consideration in the development of water quality criteria. ADSORPTION AS A CONTROL OF METAL CONCENTRATIONS IN SEDIMENT EXTRACTS,
Australian Atomic Energy Commission Research Establishment, Lucas Heights.
P. S. Rendell, G. E. Batley, and A. J. Cameron.
Environmental Science and Technology, Vol 14, No 3, p 314-318, March, 1980. 3 Fig, 5 Tab, 16 Ref.

Descriptors: *Metals, *Water analysis, Chemical analysis, *Sediments, Copper, Lead, Cadmium, Heavy metals, *Adsorption, Extraction, Sediment concentration.

Extractants spiked with copper, lead, or cadmium were shaken overnight with river sediment, and the solution metal concentrations were compared before and after the overnight extraction. To give an indication of the range of extraction reagents that might be affected, adsorption was investigated as a function of pH and in the presence of reducing agents, strong and weak complexiang agents, a weak acid, an oxidizing agent, and a cation exchanger. The adsorption of added metal in these experiments was assumed to constitute evidence for the readsorption of metal released during sediment extractions. Significant adsorption of added metal occurred during overnight extraction with dilute hydrochloric acid with a pH of more than 1.5, 0.1 M hydroxylamine hydrochloride with a pH of 2, 0.1 M sodium citrate with a pH of 4.6, 1 M ammonium acetate, 10% sodium citrate-1% sodium dithionite, and 25% acetic acid. Adsorption also occurred during a hydrogen peroxide digestion procedure. The inability of reagents to prevent losses of soluble metal in these experiments strongly suggests that a proportion of the metal actually released from a sediment sample during an extraction will be readsorbed. This may lead to serious misinterpretation of extraction data, because the metal concentrations determined in the extract do not represent metal levels in the sediment fractions attacked. (Baker-FRC)

AN ENVIRONMENTAL SAFETY ASSESSMENT OF BUTYL BENZYL PHTHALATE,
Monsanto Co., St. Louis, MO.
W. E. Gledhill, R. G. Kaley, W. J. Adams, O. Hicks, and P. R. Michael.
Environmental Science and Technology, Vol 14, No 3, p 301-305, March, 1980. 4 Tab, 26 Ref.

Descriptors: *Chemical industry, *Environmental protection, Phthalates, Safety, Environmental effects, Assessments, Water quality, Algal growth, Toxicity, Fish, *Butyl benzyl phthalate, Biodegration.

The environmental safety of butyl benzyl phthalate (BBP) was evaluated through both laboratory and field studies. BBP itself is relatively insoluble in water and tends to partition to soil, sediment, and biota in the aqueous environment. Biodegradation, the rate controlling process for environmental degradation of BBP, is rapid and extensive in natural water and sewage systems. Environmental levels of BBP averaged less than 1 microgram/liter in water and less than 100 ng/g in sediment. BBP is acutely toxic to a variety of algae, invertebrates, and fish in the 0.5 to 5 mg/liter range and chronically toxic to Daphnia and fathead minnows in the 0.1-0.8 mg/liter range. A bioconcentration study indicated that BBP was not an accumulative or persistent chemical in fish. Comparison of mean environmental water concentrations of BBP to laboratory chronic toxicity values for Daphnia and fathead minnows showed an average safety margin of about three orders of magnitude. This current safety assessment concludes that BBP under present use and disposal patterns does not constitute a hazard to the safety and well being of the aquatic environment. (Baker-FRC)

VOLTAMMETRIC CHARACTERIZATION AND CHEMICAL BEHAVIOR OF INORGANIC TIN IN NATURAL WATERS,
Istituto di Ricerca sulle Acque, Rome (Italy).
G. Macchi, and M. Pettine.
Environmental Science and Technology, Vol 14, No 7, p 815-818, July, 1980. 8 Fig, 28 Ref.

Descriptors: *Natural waters, *Tin, Seawater, Chemical analysis, Water analysis, Measuring instruments, *Volumetric analysis, Comparison studies.

Differential pulse anodic stripping voltammetry was used to test a solution containing 16 ppb of Sn(IV) in 0.04 M sodium nitrate and in artificial seawater as a function of pH. At a pH value below 7, a peak of anodic redissolution due to the oxidation of Sn(0) to Sn(II) became apparent. The peak potential shifted as a function of pH and indicated the formation of Sn(OH)(+) in the stripping process. The height of the peak decreases markedly with time in acid solution near pH 4 to 6. The results suggest that the stable forms of Sn(IV) are a function of pH. The differential pulse anodic stripping voltammetry analysis of surface seawater and samples collected at depth of 100 meters at the mouth of the Tiber River indicate the existence of Sn. The measured Sn peak was stable for at least six months. The findings indicate that soluble tin is present in natural waters in the form of Sn0(OH)3(-) when the pH is about 8. At lower values of pH, Sn may polymerize from Sn0(OH)2. (Baker-FRC)

DETERMINING VOLATILE ORGANICS IN WATER,
Monsanto Industrial Chemicals Co., St. Louis, MO.
J. P. Mieure.
Environmental Science and Technology, Vol 14, No 8, p 930-935, August, 1980. 4 Fig, 5 Tab, 19 Ref.

Descriptors: *Pollutant identification, *Organic compounds, Water analysis, Chemical analysis, Isolation.

Six techniques for low-level, multicomponent analysis of volatile organics in water are described. The key to analytical techniques for volatile organic determinations lies in the isolation step. This step determines the types of compounds to be measured, the expected accuracy and precision, and the potential interferences. Once the isolation and concentration steps have been achieved, the spectroscopic or chromatographic measurement of the analyte is usually straightforward. Static headspace sampling has detection limits ranging from sub- to mid-microgram/liter concentrations, depending on the compound and the detector. Purge and trap sampling has greater sensitivity than static headspace sampling, but foaming may be a problem. Solid sorbents have been shown effective for selected compounds, but the general usage for concentrations less than 50 micrograms/liter needs verification. Liquid/liquid extraction is useful for compounds for which specific detectors are available. Precision is better than with purge and trap technique. Sample cleanup is minimal, so removal of interferences is unlikely. Distillation is effective in concentrating water-soluble volatile organics. Semipermeable membranes are not widely used for isolation of volatiles; however, rapid analyses are possible when they are used as a selective introduction device for a mass spectrometer. (Baker-FRC)

ACCURATE AND EFFICIENT ESTIMATION OF BENTHIC POPULATIONS: A COMPARISON BETWEEN REMOVAL ESTIMATION AND CONVENTIONAL SAMPLING TECHNIQUES,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Entomology.
F. L. Carle, and O. E. Maughan.
Hydrobiologia, Vol 71, No 1/2, p 181-187, May 27, 1980. 2 Fig, 1 Tab, 5 Ref.

Descriptors: *Sampling, *Benthos, *Species diversity, Invertebrates, Biological samples, Water quality, *Bioindicators, Circular Depletion Sampler, Benthic populations.

The continuing use of benthic communities as indicators of water quality requires use of accurate and efficient quantitative sampling techniques. The removal method using the Circular Depletion Sampler (CDS) was developed to collect consecutive subsamples from the same location, increasing the probability of capture. Average probability of capture, using three subsamples, from 270 CDS samples ranged from 0.19 for Antocha to 0.96 for Chironomidae. These population estimates were higher and less variable than single removal catches, Surber catches, or kick-net catches. Although sampling time was nearly equal for all three methods, the CDS method required less than half the time to separate the benthos from the substrate. Catchability varied with species, person collecting the samples, and sampling conditions. (Cassar-FRC)

IDENTIFICATION OF ORGANIC COMPOUNDS,
NUS Corp., Pittsburgh, PA., Analytical Services Lab.
G. D. Burns.
Industrial Wastes, Vol 26, No 4, p 23-25, July/August, 1980. 6 Fig.

Descriptors: *Organic compounds, *Measuring instruments, *Chemical analysis, Wastewater analysis, Wastewater composition, *Pollutant identification.

A large increase in the usefulness of gas chromatographic/mass spectrometric analytical methods is forecast as a result of increasing demands for certain standards to be met in wastewater discharging. The basis of the identification of an unknown compound is the retention time, that is, the length of time required for the compound to elute from a specific GC column under controlled conditions of column temperature and carrier gas flow rate. Mass spectrometry offers information concerning a compound's molecular weight and structure which is not available from conventional GC detectors. Computer technology has vastly increased the capabilities of a moden GC/MS system. The cost of a GC/MS with a data system varies from bench top models for about $60,000 to a complete data system for about $250,000. (Baker-FRC)

EVALUATION OF STANDARD AND MODIFIED M-FC, MACCONKEY, AND TEEPOL MEDIA FOR MEMBRANE FILTRATION COUNTING OF FECAL COLIFORMS IN WATER,
National Inst. for Water Research Pretoria (South Africa).
W. O. K. Grabow, C. A. Hilner, and P. Coubrough.
Applied and Enviromental Microbiology, Vol 42, No 2, p 192-199, August, 1981. 13 Tab, 31 Ref.

Descriptors: *Coliforms, *Culture media, *Water analysis, Bacteria, Agars, *Fecal coliform, Microbiological studies, Rivers, Activated sludge, Performance evaluation, Pollutant identification.

Counts obtained by means of different growth media recommended for membrane filtration counting of fecal coliforms were compared and isolates were identified to establish the composition of fecal coliforms in various water environments. Media included M-FC agar, modified M-FC agar which contains no rosolic acid, Teepol media, and MacConkey agar. Comparative tests were per-

formed on 312 samples including chlorinated effluents. M-FC agar without rosolic acid generally yielded the highest counts, was readily obtainable, was easy to prepare and handle, and yielded clearly recognizable fecal coliform colonies. Fecal coliform tests cannot be used to determine E. coli levels because in these tests the incidence of E. coli among fecal colonies varies from 51% for river water to 93% for activated sludge effluent. Klebsiella pneumoniae averaged 4% for sludge effluent and 32% for river water. The standard membrane filtration procedure using M-FC agar without rosolic acid gave clear advantages. (Small-FRC)

MODIFICATION OF THE STANDARD MOST-PROBABLE-NUMBER PROCEDURE FOR FECAL COLIFORM BACTERIA IN SEAWATER AND SHELLFISH,
Food and Drug Administration, Davisville, RI. Construction Batallion Center.
F. Dexter.
Applied and Environmental Microbiology, Vol 42, No 1, p 184-185, July, 1981. 1 Tab, 2 Ref.

Descriptors: *Coliforms, *Water analysis, *Seawater, Bacterial analysis, Bacteria, Brackish water, Saline water, Shellfish.

A total of 572 seawater and shellfish samples were collected and used in a study to determine whether or not presumptive tubes which take 48 hr to become positive need to be transferred to EC medium during the fecal coliform multitube most-probable-number procedure. It appeared that incorrect dilution data would be rare when the 24 hour positive tubes alone were transferred to EC. It is suggested that when the fecal coliform multitube most-probable-number procedure is performed, the presumptive test could be discontinued after 24 hr. An exception could be made for those situations in which either extreme accuracy or a high recovery rate is necessary, for example, in a comparative study of media or techniques or both. (Baker-FRC)
W82-00646

EFFECT OF OZONATION AND CHLORINATION ON THE MUTAGENIC POTENTIAL OF DRINKING WATER,
Florence Univ. (Italy). Inst. of Pharmacology.
P. Dolara, V. Ricci, D. Burrini, and O. Griffini.
Bulletin of Environmental Contamination and Toxicology, Vol 27, No 1, p 1-6, 1981. 2 Fig, 12 Ref.

Descriptors: *Chlorination, *Ozonation, *Toxicity, Water treatment, Drinking water, Water quality, Public health, Mutagenic chemicals, *Florence, Italy.

Water from a treatment plant in Florence, Italy, was tested for mutagenic activity using the Salmonella/microsomes test. The plant treats water from the Arno River with the following treatment scheme: prechlorination, addition of powdered activated carbon, coagulation and flocculation, decanting, rapid sand filtration, ozonation, and final chlorination. Dose response curves, with and without metabolic activation, were obtained by plating different amounts of DMSO concentrates. Untreated water had a negligible mutagenic activity, whereas significant, although low, mutagenic activity was introduced by chlorination. After ozone treatment, the water showed more mutagenic activity but less than after chlorination. Ozone treatment may be an alternative to chlorination for disinfection and odor removal in water treatment. Mutagenic chemicals were produced by chlorination, while ozonation could minimize the exposure to mutagenic chemicals in drinking water. The effect of ozonation on heavily contaminated waters is not known. (Small-FRC)

NEW WATERBORNE BACTERIOPHAGES ACTIVE ON YERSINIA ENTEROCOLITICA,
Granada Univ. (Spain). Dept. of Microbiology.
C. Calvo, J. Brault, J. M. Alonso, and H. H. Mollaret.
Applied and Environmental Microbiology, Vol 42, No 1, p 35-38, July, 1981. 5 Tab, 8 Ref.

Descriptors: *Bacteriophage, *Isolation, *Bacterial analysis, Water analysis, Viruses, Surface water, Enterobacter, Bacteria, Enteric bacteria, *Granada, Spain.

A phage typing scheme for Yersinia enterocolitica (YE) was investigated using bacteriophages isolated from surface waters. Seven bacteriophages active on YE were isolated from surface water samples collected in Granada, Spain. A comparison of the respective host ranges of these new phages and of reference phages used for YE phage typing showed that YE strains belonging to various phage types, grown at either 37 or 25 degrees C, expressed susceptibility to reference sewage water phages, whereas susceptibility to new waterborne phages, as well as to reference phages from lysogenic YE, was only demonstrated in YE strains grown at 25 degrees C. A YE strain isolated by stool culture from a pig was lysogenic for a bacteriophage which behaved like waterborne phages and reference phages from lysogenic YE strains. The possibility that the isolation of waterborne bacteriophages might, in certain circumstances, reflect the presence of lysogenic YE was raised. (Baker-FRC)
W82-00662

OCCURRENCE OF CYTOPHAGAS IN SEWAGE PLANTS,
Gesellschaft fuer Biotechnologische Forschung, m.b.H., Stockheim (Germany, F.R.).
H. Gude.
Applied and Environmental Microbiology, Vol 39, No 4, p 756-763, April, 1980. 3 Fig, 5 Tab, 27 Ref.

Descriptors: *Bacteria, *Activated sludge processes, *Cytophagas, Activated sludge, Microbiological studies, Biological treatment, Wastewater treatment.

In order to better understand biological sewage purification processes, the occurrence of bacteria belonging to the Cytophaga group in activated sludge from a treatment works was investigated. Plate count methods and the KOH-flexirubin test were used to determine Cytophagas. In the inflow sewage water, the percentage of Cytophaga colonies was generally low when compared with values for activated sludge, trickling filters, and effluent samples. Over a period of 16 months, the highest percentages of cytophagas were found in activated sludge and trickling filter samples collected during the winter. Also, cytophagas were found to have high percentages of the bacteria lytic to polymeric substrates such as cellulose, chitin, dextran, pectin, xylan, and gelatin. Polymer breakdown may be the way cytophagas contribute to sewage purification, especially at low temperatures. Isolated strains of Cytophaga had gliding motility, flexirubin pigmentation, and a low guanine plus cytosine base ratio. (Small-FRC)

ORGANOCHLORINE RESIDUES IN KENYA'S RIFT VALLEY LAKES,
National Wildlife Federation, Washington, DC.
J. L. Lincer, D. Zalkind, L. H. Brown, and J. Hopcraft.
Journal of Applied Ecology, Vol 18, No 1, p 157-171, April, 1981. 1 Fig, 6 Tab, 29 Ref.

Descriptors: *Pesticide residues, *Aquatic life, *Lakes, Wildlife, Pollutant identification, Chlorinated hydrocarbons, Fish, Birds, Water birds, Insects, Invertebrates, Vegetation, Algae, Eggs, Africa, Rift Valley, Lake Nakuru, *Kenya, Fate of pollutants, DDT, DDE.

Organochlorine pesticide residues were determined in aquatic life in four Rift Valley lakes in Kenya-Naivasha, Nakuru, Baringo, and Elmenteita. These lakes are closed basin systems with no external outlet. Pesticides used in the L. Nakuru catchment basin include DDT, dieldrin, toxaphene, dioxathion, and abate (temephos). The only organochlorine detected in samples was DDE, a DDT metabolite. DDE residues in vegetation, insects, fish, amphibians, mammals, bird eggs, and bird muscle are reported for each lake. Lake Elmenteita is probably the most pesticide-contaminated of the four lakes, but the small sample sizes did not permit a definite conclusion. L. Nakuru had the highest DDE levels, with L. Naivasha and Baringo, lesser levels. Some of the higher mean levels of DDE (in mg per liter oven dry weight) were: ferns in L. Naivasha, 0.107; fish in L. Baringo, 0.43-2.13; insects in L. Baringo, 0.90; and an otter from L. Nakuru, 0.35. Residues in eggs from fish eating birds were as high as 5.75 mg per liter DDE oven dry weight in the African darter from L. Nakuru. The highest residue of DDE in avian muscle tissue was 1.09 mg per liter oven dry weight in maribou stork from L. Nakuru. (Cassar-FRC)

TOXICS IN MUNICIPAL AND INDUSTRIAL WASTEWATERS,
Municipal Environmental Research Lab., Cincinnati, OH. Wastewater Research Div.
D. F. Bishop.
In: 1980 Annual Report - A Perspective on the Problem of Hazardous Substances in the Great Lakes Basin Ecosystem, Appendix D, November, 1980. 98 p. 1 Fig, 32 Tab, 29 Ref, 3 Append. International Joint Commission, Windsor, Ontario.

Descriptors: *Hazardous materials, *Pollutant identification, Organic compounds, Waste disposal, Waste management, Waste load, Organic loading, *Industrial wastewater, Technology, Waste characteristics, Pretreatment of water, *Toxins, *Municipal wastewater, Great Lakes.

Legislative and court actions are forcing the evolution of systematic toxic management approaches to limit environmental exposure to toxics in both Canada and the United States. This report, as background to a discussion on toxic loading estimates in the Great Lakes, reviews legislative actions in the U.S. and various treatment processes studied in a 25-city survey. Approaches evaluated for the treatment of 129 'primary pollutant' compounds included removal systems, pretreatment, toxics loads, treatability, and removability. Not unexpectedly, there was a wide variation found among industrial plants for compounds identified and concentrations recorded. Similarly, removal of specific compounds varied from zero to almost 100 percent. Of the 87 compounds detected, 24 organics and 13 metals were found in all of the plants. Chlorination for disinfection generally increased the concentrations of certain compounds. The report recommends that the following issues related to municipal and industrial wastes in the Great Lakes area be studied: updating and reliability of the estimated toxics loads, municipal and industrial sources of toxics, monitoring issues, wastewater chlorination, land treatment vs. conventional wastewater treatment, and pre-treatment vs. centralized municipal treatment. (Garrison-Omniplan)

NEW LIQUID CHROMATOGRAPHIC DETECTION SYSTEM FOR ENVIRONMENTAL POLLUTANTS,
Georgia Univ., Athens.
L. A. Carreira, and L. B. Rogers.
Environmental Protection Agency Report EPA-600/4-80-015, February 1980. 71 p, 30 Fig, 3 Tab, 29 Ref.

Descriptors: *Water analysis, *Liquid chromatography, *Polychlorinated biphenyls, *Hydrocarbons, Spectrometers, Solvents, Computers, Automation, *Pollutant identification.

Resonance enhanced coherent anti-Stokes Raman spectrometry (CARS) has been demonstrated as a specific identification system for liquid chromatography. To achieve this, liquid chromatographic preconcentration and separation and computer control of the liquid chromatograph/ultraviolet-visible/CARS were undertaken. Under the optimum resonance condition, spectra were obtained on 5 microliter volumes with detection limits of 1 micromolar or less under favorable conditions. Excellent fluorescence rejection and ultraviolet

CARS were also shown. A number of different species (polynuclear aromatic hydrocarbons and polychlorinated biphenyls) were surveyed by liquid chromatography with the selectivity of different stationary phases and special solvent effects examined. Observations useful in relating experimental variables in the preconcentration step to the recovery of given species were made. A system consisting of a liquid chromatograph, a scanning ultraviolet-visible spectrometer and the CARS was automated using a mini-computer. Column selection, flow rate, and solvent composition were monitored and controlled. The ultraviolet-visible spectrometer was used at a fixed wavelenth until a species was detected. The flow was stopped, the absorption spectrum was scanned, and flow was resumed. The optimum laser frequencies for resonance CARS were set from the absorption spectrum. The Raman spectra were then scanned under control of the computer with on-line signal averaging and data smoothing. (Author's abstract)

INTERIM METHOD FOR DETERMINING ASBESTOS IN WATER,
Environmental Research Lab., Athens, GA.
C. H. Anderson, and J. M. Long.
Environmental Protection Agency Report EPA-600/4-80-005, January 1980. 43 p, 2 Fig, 2 Tab, 13 Ref.

Descriptors: *Water analysis, *Microscopic analysis, *Asbestos, *Electron microscopy, Drinking water, Filtration, Hazardous materials, Water pollution, Pollutants.

This revised interim method for asbestos in drinking water and water supplies reflects the improvements that have been made in asbestos analytical methodology since the initial procedure was drafted. A variable, known volume of water sample is filtered through a 0.1 micrometer polycarbonate membrane filter and the filter is then carbon coated. A small portion of the filter is placed on an electron microscope grid and the filter material is removed by solution in chloroform. The material remaining on the grid is examined in a transmission electron microscope at 20,000 magnification. Chrysotile asbestos can be differentiated from amphibole by their morphologies and electron diffraction patterns. The number of fibers in a known area examined in the microscope is converted to number of fibers per liter, and the mass per liter can be calculated from the assumed density and volume of the fibers. The method can detect 0.01 million fibers per liter or 0.1 ng/1, under favorable circumstances. (Brambley-SRC)

SAMPLE INTAKE POSITION AND LOADING RATES FROM NONPOINT SOURCE POLLUTION,
National Forest Service, Challis, ID.
P. E. McGuire, T. C. Daniel, D. Stoffel, and B. Andraski.
Environmental Management, Vol 4, No 1, p 73-77, January, 1980. 2 Fig, 1 Tab, 4 Ref.

Descriptors: *Nonpoint pollution sources, *Runoff, *Sampling, Water quality, Monitoring, Bed load, Suspended solids, Phosphorus compounds, Nitrogen compounds, Pollutant identification, Water sampling.

Paired water samples were taken simultaneously at two different vertical positions in a flow control structure designed for monitoring nonpoint source pollution. It was determined that easily transported pollutants and those with more potential for immediate impact on water quality should be sampled at the midstage level. If total transport of contaminants from a particular land use is required, then bed load sampling must be used. Suspended solids, total phosphorus, and organic plus exchangeable N were consistently higher when sampled at the floor of the apparatus than those sampled at midstage. Dissolved molybdate reactive phosphorus and ammonium concentrations were not significantly affected by intake position. Concentrations of nitrate-nitrite were much higher when sampled at the midstage level. Levels produced by midstage sampling, expressed as a percent of bed load (floor) sampling, were as follows: suspended solids, 44; total phpsphorus, 39; organic plus exchangeable N, 35; dissolved molybdate reactive phosphorus, 80; ammonium, 71; and nitrate-nitrite, 181. SIMULTANEOUS DETERMINATION OF IRON, CADMIUM, ZINC, COPPER, NICKEL, LEAD, AND URANIUM IN SEAWATER BY STABLE ISOTOPE DILUTION SPARK SOURCE MASS SPECTROMETRY,
National Research Council of Canada (Ontario). Div. of Chemistry.
A. P. Mykytiuk, D. S. Russell, and R. E. Sturgeon.
Analytical Chemistry, Vol 52, No 8, p 1281-1283, July, 1980. 2 Tab, 19 Ref.

Descriptors: *Seawater, *Trace elements, *Water analysis, Mass spectrometry, Chemical analysis, Copper, Iron, Zinc, Cadmium, Nickel, Lead, Uranium, Cobalt.

Seawater samples have been analyzed at trace concentration levels by stable isotope dilution spark source mass spectrometry for iron, cadmium, zinc, copper, nickel, lead, uranium, and cobalt. The samples were preconcentrated on the ion exchanger Chelex-100 and the concentrate was evaporated on a graphite or silver electrode. The results are compared with those obtained by graphite furnace atomic absorption spectrometry and inductively coupled plasma emission spectrometry. The technique avoids the use of calibration standards and is capable of producing results in cases where the analyte is only partly recovered. (Baker-FRC)

AQUATIC MOSSES AS MONITORS OF HEAVY METAL CONTAMINATION IN THE RIVER ETHEROW, GREAT BRITAIN,
Durham Univ. (England). Dept. of Botany.
P. J. Say, J. P. C. Harding, and B. A. Whitton.
Environmental Pollution, Series B, Vol 2, No 4, p 295-307, 1981. 3 Fig, 9 Tab, 13 Ref.

Descriptors: *Mosses, *Bioindicators, *Zinc, Heavy metals, Metals, Chromium, Aquatic plants, Rivers, Pollutant identification, Sediments, Water analysis, Monitoring, Etherow River, *Great Britain.

Zinc concentrations in two aquatic mosses, Fontinalis squamosa and Rhynchostegium riparioides, showed significant positive correlation, suggesting that these species may be useful bioindicators for Zn contamination of river water. Samples of water, sediments, and moss were collected on 5 occasions at 9 sites during 1979 and 1980 in the River Etherow, Great Britain, and analyzed for heavy metals. Levels of metals in sediments and water showed a similar pattern with the exception of proportionately higher lvels of Cr in sediments at 3 sites. Zn levels were 0.22 to 14.6 mg per liter in water, 73.7-4960 micrograms per g in sediments, and 64.1-6705 micrograms per g in mosses. Although Cr was not detected in water, it was present in mosses from some sites, indicating previous contamination. Data obtained for Amblystegium riparium and Fontinalis antipyretica were not sufficient to assess their value as monitors. (Cassar-FRC)

FORMATION OF N-NITROSODIETHANOLAMINE FROM DIETHANOLAMINE IN LAKE WATER AND SEWAGE,
Cornell Univ., Ithaca, NY. Dept. of Agronomy.
J. R. Yordy, and M. Alexander.
Journal of Environmental Quality, Vol 10, No 3, p 266-270, July/September, 1981. 5 Fig, 20 Ref.

Descriptors: *Wastewater, *Lakes, *Nitrosamines *Diethanolamine, Carcinogens, Nitrogen compounds, Toxins, Pollutants, Nitrite, Pollutant identification, Chromatography.

Diethanolamine (DEIA) is a compound of potential environmental concern due to its presence in a number of industrial and consumer products which result in the dicharge of large amounts of the unchanged chemical into wastewater and sewage. The N-niroso derivative of DEIA, N-nitrosodiethanolamine (NDEIA), is a proven carcinogen. This study used a thin-layer chromatographic technique with a carbon-14 labeled secondary amine to measure the possible formation of nitrosamines in samples of natural waters and sewage. The loer limit of sensitivity was 1 nanogram of nitrosamine per milliliter. The formation of NDEIA from DEIA in both lake waters and sewage was demonstrated. A combination of gas chromatography and mass spectrometry was used to verify the ientity of the product. Sewage produced the greatest amount of the carcinogenic NDEIA, while water from Cayuga Lake produced considerably less. The least amount of NDEIA was produced by water from an acid lake. The amount of DEIA added and the nitrite level in samples of the environment were found to be related to the amount of the nitrosamine formed. When samples of sewage and water from Cayuga Lake were autoclaved, NDEIA was either not formed or formed at rates much lower than in nonsterile environments. These results indicate that microorganisms or some other heat-labile factor may play a role in the formation of the nitroso compound. Although the nitrosamine could be netabolized in all three environments investigated, it persisted in lake water samples taken in the winter. (Carroll-FRC)

MEASUREMENT OF IN SITU RATES OF NITRIFICATION IN SEDIMENT,
Aarhus Univ. (Denmark). Inst. of Ecology and Genetics.
K. Henriksen.
Microbial Ecology, Vol 6, No 4, p 329-337, 1980. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Nitrification, *Sediments, *Chemical reactions, Ammonium, Sediment sampler, Inhibitors, In situ tests, Oxygen, Bacteria, Chemical analyses, *Marine sediments.

High numbers of nitrifying bacteria occur below the zone of oxygen penetration in marine sediments and can almost immediately oxidize ammonium when supplied with oxygen. As a result, sampling methods which introduce oxygen into anoxic parts of the sediment can be expected to give potential rather than actual nitrification rates. This paper reports the development of a method for the measurement of nitrification rates in intact sediment cores without disturbing the concentration gradients of oxygen and ammonium. N-serve (2-chloro-6-trichloromethyl-pyridine) is a specific inhibitor of the nitrifying bacteria Nitrosomonas in oxidizing ammonium to hydroxylamine, the first step in the nitrification process. Injection of 20 parts per million (ppm) of N-serve into a 0-2 centimeter surface layer of the sediment and addition of 5 ppm N-serve to the water column of sediment cores was sufficient to inhibit nitrification, but did not change the rate of ammonium production or incorporation in sediment suspensions. The sediments were incubated aerobically and anaerobically. The ammonium accumulation in sediment cores injected with N-serve was equal to the amount of ammonium which was oxidized to nitrate in the control cores. Nitrification rates measured by this method were in the range of 0 to 3 millimolecules of nitrogen per square meter per day. The agreement of this finding with the findings of previous studies substantiates the conclusion that this method gives near in situ nitrification rates. (Carroll-FRC)

SAMPLING GROUND WATER FOR ORGANIC CONTAMINANTS,
Oklahoma State Univ., Stillwater. Dept. of Geology.
W. A. Pettyjohn, W. J. Dunlap, R. Cosby, and J. W. Keeley.
Ground Water, Vol 19, No 2, p 180-189, March/April, 1981. 8 Fig, 7 Ref.

Descriptors: *Water sampling, *Groundwater pollution, *Laboratory equipment, Water quality, Wells, Sampling, Sample preparation, Pollutant identification.

Current preferred methods for the sampling of organic pollutants in groundwater are described which are used at the Ground Water Research Branch of the Robert S. Kerr Environmental Research Laboratory. For an effective sampling program, sampling equipment must be constructed of materials that have the least potential for affecting the sample, including glass and Teflon. Wells used to sample groundwater should be drilled and completed using techniques that minimize potential contamination of the aquifer. Teflon tubing can be used to case that portion of the well that extends from a few feet above the water table to the bottom of the borehole. Grab samples can be withdrawn through a sterile 6 mm Teflon tube and discharged into a sterile, calibrated one-liter heavy-wall Erlenmeyer flask with a peristaltic pump. For sampling at greater depths, a noncontaminating submersible high-lift pump can be used. Continuous sampling can utilize a system in which the water is pumped directly from the well through 6 mm Teflon tubing to two columns of adsorbent in series. Sampling systems are installed in specially constructed housings and form self-contained, easily transported units. (Small-FRC)

A REDUCTION-SPECTROPHOTOMETRIC METHOD FOR THE DETERMINATION OF SULPHATE IN WATERS,
Sydney Univ. (Australia). Dept. of Inorganic Chemistry.
Rama S. Bhat, J. M. Echert, and N. A. Gibson.
Analytica Chimica Acta, Vol. 128, p 263-267, 1981. 2 Tab, 7 Ref.

Descriptors: *Water analysis, *Sulfates, Estuarine environment, Seawater, Natural waters, Chemical analysis, *Spectrophotometry.

The reduction spectrophotometric method presented for the determination of sulfate in waters is based on the reduction of the sulfate by tin(II) chloride in hydriodic acid to hydrogen sulfide, which is then swept by nitrogen into a buffered solution of bis(2,9-dimethyl-1,10-phenanthroline)copper(II) ion. The resulting copper(I) complex is measured spectrophotometrically. With sample volumes between 10 and 1000 microliters, the limit of detection is 0.5 micrograms of sulfate. Formation of the stable complex is immediate and the reduction system can be used repeatedly. The method is applicable to fresh, estuarine, and marine waters. The common inorganic sulfur containing anions such as sulfide, sulfite, thiosulfate, tetrathionate and dithionate interfere quantitatively with the proposed method, as they are all reduced by hydrogen sulfide with the same efficiency as sulfate. No interference was present from linear alkylbenzene sulfonates. The major ions of sea water do not intefere seriously, and the method may be used without modification for the determination of sulfate in marine and estuarine waters. (Baker-FRC)

EVALUATION OF AN AUTOMATIC SYSTEM FOR DETECTION OF TOXIC SUBSTANCES IN SURFACE WATER USING TROUT,
Antwerpse Waterwerken (Belgium).
F. Van Hoof.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 2, p 221-225, 1980. 2 Tab, 10 Ref.

Descriptors: *Toxicity, *Bioindicators, *Monitoring, *Trout, Fish physiology, Water pollution, Experimental design, Chemical analysis, *Surface water, Streams, Sewage treatment, Environmental effects, Metabolism, Sewage effluent.

An automatic system for detection of toxic substances in surface water is evaluated. The system uses rainbow trout as test organisms, since toxicity data on fish can be more easily extrapolated to mammals than results obtained with organisms having a lower level of bioorganization. Fish in aquaria were exposed to eight chemicals representing widely used pesticides and other polluting discharges. Avoidance reactions, loss of condition or death were monitored by a set of photoelectric cells placed at the downstream end of the flow-through aquarium. No conclusive evidence of toxicity was observed for cadmium, zinc, and ethyl-parathion. Potassium cyanide was the only product to elicit a clear avoidance response. Carbaryl, malathion, dinitroorthocresol, and captan caused death. These results are used in calculations of lethal dose concentrations; however, they do not take into account any safety margin. The biomonitoring parameters, i.e., positive rheotaxis and opercular rhythm in fish, oxygen production and oxygen consumption in bacteria, and mobility inhibition in daphnia may be useful when results from flow-through monitoring are inadequate. DETECTION OF VOLATILE NITROSAMINES IN WASTE WATER FROM CHEMICAL PLANTS BY COMBINED CAPILLARY GAS CHROMATOGRAPHY-MASS SPECTROMETRY,
Mainz Univ. (Germany, F.R.). Hygiene Inst.
G. Hartmetz, and J. Slemrova.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 1, p 106-112, 1980. 4 Fig, 2 Tab, 10 Ref.

Descriptors: *Volatility, *Waste water, *Chemical wastes, *Mass spectrometry, *Gas Chromatography, Industrial wastes, Carcinogens, Drinking water, Potable water, Water treatment, Water sampling, Chemical analysis, Sea water, Brackish water, Chemical wastewater, Pharmaceutical wastewater.

Seven samples of crude water from different wastewater treatment facilities and the purified waste water from a chemical-pharmaceutical plant were examined for carcinogenic materials. Concentrations of nitrosamines in the purification works effluent varied considerably with time. Findings show that volatile nitrosamines are introduced into the surface water through the waste water of chemical plants. The nitrosamine concentrations in the waste water are of the same order of magnitude as in various foodstuffs. Concentrations are so dilute in rivers as to be undetectable. (Titus-FRC)

SERUM ENZYMES IN RAINBOW TROUT AS TOOLS IN THE DIAGNOSIS OF WATER QUALITY,
Innsbruck Univ. (Austria). Inst. fuer Zoophysiologie.
W. Wieser, and S. Hinterleitner.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 2, p 188-193, 1980. 1 Tab, 15 Ref.

Descriptors: *Fish physiology, *Blood, *Toxicity, *Bioindicators, Water pollution, Experimental design, Chemical analysis, Trout, Streams, Sewage treatment, Environmental effects, Enzymes, Metabolism, Ammonia, Nitrate, Nitrite, *Sewage effluent, Water pollution effects.

Stress responses of trout (Salmo gairdneri) brought about by deterioration of water quality are investigated. The activities of two transaminases in the trout serum were measured and the quality of the river water was analyzed at areas where the fish were caught. Samples were obtained at various distances from a sewage outfall. The transaminase activity was found to be a function of distance from the sewageplant and to be correlated with the nitrogen content of the river water. The behavior and appearance of liver and gills of fish showed no variation from normal. Specimens caught within the plume had high values of serum glutamic oxalacetate transaminase (SGOT) and glutamic pyruvate transaminase (GPT) activity. The levels of SGOT and SGPT activity in S. gairdneri appear to be good indicators of certain types of water pollution, at least within a range characterized by total ammonia concentrations of approximately 0.5 to 12 mg/liter. Trout in natural waters, in contrast to laboratory conditions, appear to tolerate surprisingly high local pollutant concentrations. (Titus-FRC)

METHODS OF INVESTIGATING THE STATE OF METAL IONS IN NATURAL WATERS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
P. N. Linnik, and B. I. Nabivanets.
Water Resources (English Translation), Vol 7, No 5, p 463-477, September/October, 1980. 3 Fig, 1 Tab, 162 Ref. Translated from Vodnye Resursy, No 5, p 148-170, September/October, 1980.

Descriptors: *Metals, *Water analysis, *Measurement techniques, *Ions, Colloids, Suspended solids, Dissolved solids, Chemical analysis, Physical analysis, Separation techniques, Ionization, Hydrolysis, Oxidation.

Information concerning the forms of metal ions in natural waters is needed for developing an understanding of mechanisms for the assimilation of metals by aquatic organisms, for developing hydrochemical methods of prospecting for mineral resources, and for developing effective water treatment processes. This state-of-the-art review describes methods being used for the investigation and quantification of the forms of migration of metals in natural waters, including the distribution of metal between suspended, colloidal, and truly dissolved forms; the concentration of free noncomplexed ions of the investigated metals; the sign of the charge of the metal ions; the molecular (ionic) weight of complex or polynuclear compounds; complexation of metal ions in natural waters (kinetics of complexation, degree of complexation, strength of binding the metal into complex compounds, and complexing capacity of natural waters); and degree of oxidation (Valency) of the metal. The possibilities and limitations of each of the measurement techniques described are discussed. It is now possible to create general schemes for a systematic study of forms of migration of metal in complex natural waters. Three such general schemes are discussed. One of these schemes, developed by the authors of the article, permits the development of information on the state of metal ions in natural waters which is sufficiently complete to satisfy the needs of various specialists engaged in the problems of the study and use of natural waters. This scheme includes the successive use of various methods of investigation, permitting a quantitative determination of the portion of individual forms of the investigated element. (Carroll-FRC)

EFFECT OF TURBIDITY ON CHLORINATION EFFICIENCY AND BACTERIAL PERSISTENCE IN DRINKING WATER,
Oregon State Univ., Corvallis. Dept. of Microbiology.
M. W. LeChevallier, T. M. Evans, and R. J. Seidler.
Applied and Environmental Microbiology, Vol. 42, No. 1, p 159-167, July, 1981. 7 Fig, 1 Tab, 29 Ref.

Descriptors: *Drinking water, *Turbidity, *Chlorination, Disinfection, *Bacteria, Water quality, Potable water.

The influence of turbidity on drinking water quality was examined in six watersheds where turbidities at entry points to distribution lines ranged from 0.2 to 15.0 nephelometric turbidity units (NTU). Coliforms densities in raw water ranged from 11 to 500 coliforms per 100 ml, and were reduced 10- to

1,000-fold by chlorination. Coliforms in high-turbidity water (13 NTU) were reduced to only 20% of the initial count, whereas coliforms in low turbidity water (1.5 NTU) were undetectable even when large volumes were sampled, indicating a 1,000-fold or greater decrease. Disinfection efficiency was found to be negatively correlated with turbidity. Turbid water samples were examined in an attempt to determine factors which aid bacteria in surviving exposure to chlorine. Some bacteria particles were either embedded in trubidity particles or appeared to be coated with amorphous material or both. Blending of chlorinated turbid water increased the number of standard plate count bacteria as much as five times, indicating the physical separation of cells attached to common particles. The chlorine demand of the surfce water supplies was positively correlated with both the turbidity and total organic carbon content of the water, but not with other chemical parameters. It was concluded that turbidity is a useful indicator of potential problems in drinking water. (Baker-FRC)

GOOD LOOKS, LOW MAINTENANCE GUIDE WATER TANK CHOICE,
K. Grover.
American City and County, Vol. 95, No. 12, p 19-22, December, 1980.

Descriptors: *Water tanks, *Water storage, *Maintenance costs, *Design criteria, *Concrete construction, Storage tanks, Pipes, Materials engineering, Cost analysis, Economic aspects, Design standards, Pumps, Pumpage, Construction, Construction costs.

The design and cost of various water tanks is discussed, and examples of tanks currently in operation are cited. The three basic types of tanks used today are ground storage reservoirs, standpipes, and elevated tanks. Steel and concrete are the standard construction materials. For utilities and districts with storage needs in excess of 1.5 million gallons, tanks are constructed of welded steel or prestressed concrete, while bolted steel is appropriate for smaller tanks. Topography of the service area, availability and cost of land, and the type of water system are the prime factors influencing the choice of design. Elevated tanks assure constant pressure, accommodate variable demand, and can reduce pumpage costs. Standpipes are useful where there is some need for pressure equalization. Ground storage often offers lowest first cost and maintenance costs. It is safer and more convenient, and avoids aesthetic problems. However, land acquisition and excavation costs may be high. The newest innovation in design is the multi-use elevated tank which provides space inside for offices, pumps, controls, and storage. These are in operation in over 100 towns in the United States. DETERMINATION OF LOW NG/L LEVELS OF POLYCHLORINATED BIPHENYLS IN DRINKING WATER BY EXTRACTION WITH MACRORETICULAR RESIN AND ANALYSIS USING A CAPILLARY COLUMN,
Environmental Health Directorate, Ottawa (Ontario).
G. L. LeBel, and D. T. Williams.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 3, p 397-403, 1980. 3 Fig, 2 Tab, 14 Ref.

Descriptors: *Drinking water, *Phenols, *Organic compounds, Water pollution, Contamination, Potable water, Streams, Groundwater, Chlorination, Chlorine, Gas chromatography, Water sampling, Monitoring, Experimental design, *Pollutant identification, *Polychlorinated biphenyls.

The application of the XAD-2 macroreticular method to analyze large volumes of potable water for low volumes of polychlorinated biphenyls was investigated. Contributions to the procedural blank value and the interference from other organic materials in a water sample were examined. Quantitation of recovery runs was achieved by comparing peak heights of selected peaks from the sample extracts with the corresponding peaks from standard polychlorinated biphenyl solutions. Results of tests run on well samples indicate that the detection limits are affected by the interference from other organics in the water sample but are typically in the 1 to 10 microgram per liter range for potable water from a river source. (Titus-FRC)
W82-00875

OCCURRENCE OF TETRAALKYLEAD COMPOUNDS IN THE AQUATIC ENVIRONMENT,
Canada Centre for Inland Waters, Burlington (Ontario).
Y. K. Chau, P. T. S. Wong, O. Kramar, G. A. Bengert, and R. B. Cruz.
Bulletin of Environmental Contamination and Toxicology, Vol. 24, No 2, p 265-269, 1980. 1 Tab, 10 Ref.

Descriptors: *Aquatic environment, *Fish physiology, Fish populations, *Water pollution, *Toxicity, Microorganisms, *Lead, Organic compounds, Primary productivity, Environmental effects, Ecosystems, Gas chromatography, Spectrophotometry, Sediment, Lakes, *Tetraalkylead compounds.

Results of an extensive survey of fish, vegetation, sediment, and water for the presence of tetraalkylead compounds are presented. The samples were taken from various lakes and rivers in Ontario. Only fish samples were found to contain these compounds. The source of these compounds is thought to be antiknock gasoline additives or related commercial products. The fish containing tetraalkylead also contained high total and extractable lead. No relationship between species and size of fish and concentration of pollutant was detected. The type of tetraalkylead varied in different locations. Concentrations of the tetraalkylead were generally low, comprising less than 10 per cent of the total lead. (titus-FRC)

DETERMINATION OF POLYHALOGENATED PHENOLIC COMPOUNDS IN DRINKING WATER, HUMAN BLOOD SERUM AND ADIPOSE TISSUE,
Miami Univ., FL. School of Medicine.
C. Morgade, A. Barquet, and C. D. Pfaffenberger.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 2, p 257-264, 1980. 5 Tab, 8 Ref.

Descriptors: *Phenols, *Drinking water, *Halogens, *Tissue analysis, *Water sampling, Potable water, Organic compounds, Blood, Experimental design, Water pollution, Gas chromatography, Sensitivity analysis, Public health.

The blood serum of 58 women in Florida was analyzed for the presence of eight halogenated phenols, and the drinking water source for each woman was recorded. Chlorinated municipal water and nonchlorinated well water were the two sources of drinking water. Additionally, 10 samples of human adipose tissue, taken at autopsy, were analyzed. Results showed that blood serum levels of PCP were not dramatically different for the two groups of women. The concentrations in both groups were significantly below those reported for citizens in Hawaii. Tissue analyses indicate that PCP (pentachlorophenol) does not bioconcentrate in human adipose tissue to the same extent as DDT and DDE. The level of PCP in adipose tissue ranged from 0.01 to 0.08 parts per million. (Titus-FRC)

ALUMINUM SHADOWING-DIRECT PROJECTION PHOTOMICROSCOPY OF DIATOM FRUSTULES,
Weyerhaeuser Co., Longview, WA.
D. W. Quackenbush, and M. L. Bothwell.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 7, p 1160-1166, July, 1980. 3 Fig, 24 Ref.

Descriptors: *Diatoms, *Microscopy, Bacteria, Phytoplankton, *Photography, Water analysis, *Environmental gradient, *Ecology.

Accurate identification of diatom genera and species represents an important means of studying present and past environmental conditions in freshwater and marine ecosystems. The aluminum shadowing-direct projection method produced high resolution photomicrographic reproductions of diatom preparations in the 200 x 800 magnification range. This technique, which allows size determination in three dimensions, provides a simple and inexpensive alternative to low magnification scanning electron micrographs. Among the details revealed are valve surface contours, ridges and depressions, raised and depressed central areas of Cyclotella valves, external and internal valve views of pennate forms, and puncta of Stauroneis. A shadowing angle of 20 degrees gave the best results. By multiplying the measured length of shadows by tan 20 degrees, the depth of specimens or length of spines can be determined. Diatom identification and enumeration can be done directly from photographic prints, which are a permanent record. Another potential use of the method is in preparing permanent mounts for total free-living bacteria counts of water samples. (Cassar-FRC)

GRAB VERSUS COMPOSITE SAMPLING: A PRIMER FOR THE MANAGER AND ENGINEER,
Illinois Environmental Protection Agency, Springfield.
D. J. Schaeffer, H. W. Kerster, and K. G. Janardan.
Environmental Management, Vol 4, No 2, p 157-163, March, 1980. 1 Tab, 7 Ref.

Descriptors: Sampling, *Water sampling, Water quality management, Effluents, Wastewater treatment, Monitoring, Regulations, Pollutant identification, Water analysis, Water pollution prevention, Simulation analysis, *Wastewater analysis, *Comparison analysis, Sampling techniques.

Effluent samples are usually aggregated into 24-hr composite samples for measuring compliance. This paper shows by simulation analysis that random grab samples are as effective as composite samples for monitoring purposes and provide more information on plant variability. In addition, by using a constant volume compositing regime, a single composite of n subsamples provides as much information as do n grab samples. Monthly average performance measured by M composites is the same as that measured by M random grabs taken over the same period. M grab samples are equally or more informative than the monthly average derived from flow proportional composites. For judging average plant performance, composites are better than grabs; for long term performance, grabs and composites provide the same real information. Process extremes, particularly high values, are more readily revealed by grab samples than by composite samples. This allows earlier corrective measures for out-of-control plant operations and warnings on releases of momentarily high concentrations of toxic or high BOD effluents. (Cassar-FRC)

LIBRARY U. OF ILLINOIS URBANA-CHAMPAIGN

Descriptors: *Cadmium, *Bioindicators, *Behavior, *Crayfish, Invertebrates, Monitoring, Water quality, Metals, Animal behavior, Water pollution effects, Aquatic environment, Pollutant identification.

Crayfish (Cambarus acuminatus) were able to detect sublethal concentrations of cadmium and respond by changing their locomotion patterns. This suggests a possible use of crayfish in continuous biomonitoring systems. The alterations in locomotor patterns included: activity without directed movement, momentary cessation of directed movement at the contaminated-uncontaminated interface, attempts to leave the test chamber, and leaving and reentering the Cd zone. Tests were conducted in tanks using Cd concentrations of 125.0, 12.5, and 1.25 micrograms per liter. The crayfish tended to avoid the Cd area in the tank with the highest concentration and appeared to prefer the Cd side in the lower two concentrations. A possible explanation for this is that the pollutant disrupts chemosensory behavior, blocking taste receptors and natural stimuli. (Cassar-FRC)

HEAVY METAL CONCENTRATIONS IN THE HOLSTON RIVER BASIN (TENNESSEE),
East Tennessee State Univ., Kingsport. Dept. of Chemistry.
G. J. Young, and R. D. Blevins.
Archives of Environmental Contamination and Toxicology, Vol 10, No 5, p 541-560, September, 1981. 1 Fig, 7 Tab, 71 Ref.

Descriptors: *Heavy metals, *Water analysis, *Fish, Monitoring, Pollutant identification, Metals, Cadmium, Lead, Manganese, Zinc, Copper, Mercury, *Holston River, *Tennessee, Water pollution sources, Toxicity, Water pollution effects.

Heavy metals (Zn, Cd, Hg, Cu, Pb, and Mn) were measured in water samples and fish muscle from the Holston River Basin in Eastern Tennessee. This basin, encompassing 12 counties, contains both natural, unpolluted streams and waters heavily polluted by industrial and domestic uses. Maximum levels (in ppb) in water samples were: Zn, 1143; Mn, 637; Pb, 18; Hg, 0.6; Cd, 4; Cu, 68. In fish muscle maximum levels (in ppm) were: Cd, 0.41; Pb, 1.3; Mn, 4.3; Cu, 0.8; and Zn, 24. Median levels of Cd, Cu, Pb, and Zn in the Holston River Basin were at or below median values found in fish throughout the world; Mn levels were much higher. Serious Hg pollution problems downstream of a chlor-alkali plant operated from 1950 to 1972 were not reflected in grab water samples because large amounts of Hg are adsorbed on sediment. Fish muscle is a better indicator of Hg pollution than water samples. (Cassar-FRC)

SEA URCHIN SPERM BIOASSAY FOR SEWAGE AND CHLORINATED SEAWATER AND ITS RELATION TO FISH BIOASSAYS,
Washington Univ., Seattle. Fisheries Research Inst.
P. A. Dinnel, Q. J. Stober, and D. H. DiJulio.
Marine Environmental Research, Vol 5, No 2, p 29-39, 1981. 3 Fig, 2 Tab, 30 Ref.

Descriptors: *Bioassay, *Wastewater, *Echinoderms, Chlorination, Toxicity, *Seawater, Eggs, Fertilization.

Sea urchin sperm bioassay was used to assess the toxicity of a complex municipal wastewater and chlorinated seawater, and these results were compared with previous results obtained with fish. Green sea urchin or sand dollar sperm and eggs were exposed to chlorinated or unchlorinated primary sewage effluent or chlorinated seawater before fertilization of eggs. With 5-minute exposures to chlorinated sewage, eggs remained viable in up to 25% sewage while sperm viability decreased to 29% in 5% sewage and 0% in more than 10% sewage. Fertilization was successful after 5-minute exposures of the sperm to as much as 30% freshwater in seawater with a salinity of about 20 ppt, while sperm lost viability in 20% sewage/seawater dilutions. Fertilization success was reduced by 50% by 2.2% chlorinated or 4.8% unchlorinated sewage in seawater. Sea urchin and sand dollar sperm were more sensitive than marine fish sperm to sewage and chlorinated seawater. Tests with sperm cells require only short exposure times under static conditions, thus this bioassay technique may be useful to researchers. (Small-FRC)

DETERMINATION OF PICOGRAM AMOUNTS OF TECHNETIUM-99 BY RESIN BEAD MASS SPECTROMETRIC ISOTOPE DILUTION,
DuPont de Nemours (E. I.) and Co., Aiken, SC. Savannah River Lab.
T. J. Anderson, and R. L. Walker.
Analytical Chemistry, Vol 52, No 4, p 709-713, April, 1980. 3 Fig, 3 Tab, 25 Ref.

Descriptors: *Nuclear powerplants, *Isotope studies, *Mass spectrometry, Resins, Radioisotopes, *Pollutant identification, Chemical analysis.

Accumulation of large amounts of technetium-99, which is produced in high yields from the fission of uranium-235 and plutonium-239, can be expected to occur concurrent with energy production by atomic fission. The volatility of technetium-99 and its aqueous mobility in soil systems create the potential for escape to the environment. This paper reports the development of an improved isotope dilution mass spectrometric technique for the analysis of technetium-99 in environmental samples. Sequential ion-exchange chromatography and ion-association solvent extraction are used to isolate technetium from a sample spiked with technetium-97. The isolated technetium is concentrated onto a pair of anion exchange beads having a diameter of about 0.3 millimeters, which are then individually analyzed on the rhenium 'V' filaments of a surface-ionization mass spectrometer. The resin bead source provides an enhanced ionization efficiency capable of permitting determination of as little as 1 picogram of technetium. This technique was used for the analysis of several environmental samples from the vicinity of the Savannah River Plant, a nuclear materials production complex. These analyses showed that technetium-99 has high mobility in water-saturated soil and that technetium-99 concentrations in the seepage basins can be expected to vary substantially with reprocessing parameters. The contribution of technetium-99 to the Savannah river was assessed by comparing upstream and downstream samples and gave an annualized instantaneous release rate to the aqueous environment of 0.05 Ci/yr. A RAPID SIMPLE LONG-TERM TOXICITY ASSAY FOR AQUATIC CONTAMINANTS USING THE NEMATODE PANAGRELLUS REDIVIVUS,
Manitoba Univ., Winnipeg. Dept. of Zoology.
M. R. Samoiloff, S. Schulz, Y. Jordan, K. Denich, and E. Arnott.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 7, p 1167-1174, July, 1980. 6 Tab, 10 Ref.

Descriptors: *Bioassays, *Water pollution effects, *Nematodes, Carcinogens, Aquatic animals, *Heavy metals, Toxicity, Pesticide toxicity, Pesticides, Physiological ecology, Water pollution, Assay, Bioindicators.

Two bioassay methods (one developmental, the other mutagenic) for determining the effects of aquatic environmental contaminants to the nematode Panagrellus redivivus are presented. The nematodes were tested with 15 known carcinogens or mutagens, 6 suspect carcinogens, and 7 heavy metals at levels of 0.01 to 1,000 micromoles/liter. An assay based on frequency of completion of postembryonic molts showed that 24 of the 28 test agents caused an increased mortality to P. redivivus. Twelve of the known carcinogens and one heavy metal caused lethal mutations in nematode chromosome assays. These assays are recommended for the detection of toxic effects to aquatic organisms due to chronic exposure to environmental water pollutants. (Geiger-FRC)

RELATION BETWEEN TROPHIC POSITION AND MERCURY ACCUMULATION AMONG FISHES FROM THE TONGUE RIVER RESERVOIR, MONTANA,
Montana Cooperative Fishery Research Unit, Bozeman.
G. R. Phillips, T. E. Lenhart, and R. W. Gregory.
Environmental Research, Vol 22, No 1, p 73-80, June, 1980. 3 Fig, 30 Ref.

Descriptors: *Reservoirs, *Fish, *Mercury, Toxicity, Accumulation, *Bioaccumulation, Methylmercury, Organic compounds, Mining industry, *Tongue River Reservoir, *Montana.

Fish were collected from the Tongue River Reservoir during spring and summer 1978 using trap nets or gill nets. Total mercury in fish was determined using an atomic absorption spectrophotometer. Mercury concentrations in muscle tissue from all five species of fish increased with fish length. This increase in contamination with increasing length is primarily a result of the long biological half-time of methylmercury in fishes. Male northern pike contained higher mercury concentrations than did females of similar length. This trend was a result of the slower growth of males relative to females. Mercury concentrations in some individuals of all species analyzed exceeded the FDA guideline. Maximum mercury concentrations in microgram mercury/gram observed were as follows: Northern pike 1.53, sauger 1.40, walleye 1.30, black crappie 0.64, and white crappie 0.60. Mercury concentrations in northern pike were particularly high, with 29% of the fish analyzed exceeding the FDA guidelines. Northern pike and saugers accumulated mercury nearly twice as fast as did the two species of crappie. The rate for walleyes was intermediate. It was concluded that planktivores derive most of their methylmercury body burden from water, but that piscivores receive a significant amount from both diet and water. (Baker-FRC)

DISPERSAL OF SALMONELLA FROM A POLLUTED STREAM TO NEIGHBORING TERRESTRIAL HABITATS,
Elmhurst Coll., IL. Dept. of Biology.
F. C. Mittermeyer, D. Cramer, and R. Ransford.
Journal of Environmental Science and Health, Part A, Vol 15, No 3, p 269-281, 1980. 1 Fig, 1 Tab, 8 Ref.

Descriptors: *Human diseases, *Salmonella, *Bacterial analysis, Rivers, Surface waters, Sediments, Shores, Shoreline cover, Soil analysis, Bacteria, River water, Water pollution sources, Path of pollutants, *Illinois.

Environmental samples were collected from the Fox River and adjacent areas in Kane County, Illinois. Seven sampling sites were chosen from within the suburban municipalities of St. Charles, Geneva, Batavia, and North Aurora. During the first four months of the study the greatest efficiency of Salmonella recovery was achieved using BPW pre-enrichment followed by enrichment in BGTET and subsequent plating onto Brilliant Green Agar. This procedure was used exclusively thereafter. Twenty-three percent of grass samples taken from the river's edge were positive for Salmonella. Grass samples taken more than 2 meters from the river were all negative. Soil samples taken from the top 10 cm of the ground about 3 meters from shoreline were usually negative. Salmonella heidelberg was the only serotype found in the sediment samples. Attempts to isolate Salmonella from surface swabs of picnic tables, trees, poles, bridges, and other surfaces within 15 meters of the river were unsuccessful. Some animals associated with the polluted river were found to be infected with Salmonella. However, general findings lead to the conclusion that the river is not an intensive Salmonella threat to humans, except perhaps those who directly contact the water. (Baker-FRC)

GIARDIA PREVALENCE IN COMMERCIALLY TRAPPED MAMMALS,
Washington State Dept. of Social and Health Services, Olympia. Office of Environmental Programs.
F. Frost, B. Plan, and B. Liechty.
Journal of Environmental Health, Vol 42, No 5, p 245-249, March/April, 1980. 5 Tab, 13 Ref.

Descriptors: *Water quality, *Drinking water, Giardia, Watersheds, Parasites, Potable water, *Contamination, Public health, Water pollution sources, Mammals, Protozoa, Chlorination, Beaver, Epidemiology, *Municipal water, Animal parasites.

Several recent outbreaks of giardiasis have been linked to the presence of Giardia in municipal water supplies. In most cases human or animal contamination of drinking water has been implicated. Since chlorine may not be effective in inactivating cysts, the risk of human infection through contaminated drinking water may be significant. Commercial trappers were recruited to provide stool samples from kill-trapped animals. During the three years of the study 704 fecal samples were examined. Parasites were found in all species of animals; however, only the beaver and muskrat harbored Giardia. The percentage of Giardia-positive animals increased each year, due to the detection of infected animals in previously negative counties and to a higher prevalence of Giardia infections in animals from previously positive counties. In the second and third years, Giardia prevalence in muskrats was higher than in beavers. The finding of infected animals in the Jones Creek/Boulder Creek, Cedar River and Green River watersheds suggests that beavers can maintain the infection independent of human involvement. This indicates that human sewage is not necessary to maintain infections among wild beaver. It also suggests that protected watersheds will not insure pathogen-free water. (Baker-FRC)

BIOLOGICAL TESTING METHODS - COMPLIANCE WITH HAZARDOUS WASTE REGULATION CHAPTER 173-302 WAC.
Washington State Dept. of Ecology, Olympia.
Document DOE 80-12, October, 1980. 24 p, 1 Fig, 3 Tab.

Descriptors: *Fishkill, *Waste characteristics, *Hazardous materials, *Waste identification, *Fish toxins, Fish populations, Testing procedures, Toxicity, Test facilities, Poisons, Mortality, Lethal limit, Laboratory animals, *Washington.

The purpose of Washington's acute fish toxicity test is to provide a simple, reliable, low-cost method for testing the toxicity of a material against the requirements of the Hazardous Waste Regulation, Chapter 173-302 WAC. The test method developed, described in Part A of the report, is strictly a range-finding test and does not determine the actual median lethal concentration, which is defined as the concentration of material that kills 50 percent of the population (fish) within 96 hours. The method, incorporating test organisms in holding tanks in a constant-temperature room or recirculating water batch, follows the requirements of Chapter 173-302 WAC, which states that if the toxicity is not known, the waste must be tested at two concentrations: 100 mg/l and 1000 mg/l. Wastes that are highly toxic and kill fish at 100 mg/l are considered extremely hazardous, while wastes that kill fish at 1000 mg/l are considered dangerous wastes. Part B of the report describes oral rat testing whose purpose is to determine the relative biological risk of potentially hazardous waste to man and wildlife. Male albino rats weighing 200-300 grams are used for test and control animals. Wastes are introduced into the stomachs by a tube. Ten rats are used at each dosage level, and ten rats for each positive control test. Oral rat tests are used whenever a generator does not characterize the toxicity of a waste because of a lack of knowledge of the chemical composition and presence of toxic constituents, a lack of knowledge of the biological hazards of toxic constituents or the waste as a whole, and/or the inability to book-designate a waste's biological toxicity. DETERMINATION OF ALKALINE EARTH AND DIVALENT TRANSITION METAL CATIONS BY ION CHROMATOGRAPHY WITH SULFATE-SUPPRESSED BARIUM AND LEAD ELUENTS,
Brigham Young Univ., Provo, UT. Dept. of Chemistry.
F. R. Nordmeye, L. D. Hansen, D. J. Eatough, D. K. Rollins, and J. D. Lamb.
Analytical Chemistry, Vol 52, No 6, p 852-856, May, 1980. 2 Fig, 5 Tab, 8 Ref.

Descriptors: *Water analysis, *Metals, Magnesium, Calcium, Strontium, Iron, Manganese, Cobalt, Nickel, Copper, Zinc, Cadmium, Lakes, Ponds, Measuring instruments, *Chromatography.

The development of simple eluent-suppressor systems is reported. These systems allow the simultaneous ion chromatographic determination of Mg(2+), Ca(2+), and Sr(2+), and individual determinations of Mn(2+), Fe(2+), Co(2+), Ni(2+), Cu(2+), Zn(2+), and Cd(2+). Aqueous Ba(2+) and Pb(2+) which serve as eluting ions are suppressed as insoluble sulfates in a suppressor column initially loaded with SO4(2-). An H(+)-exchange postcolumn is placed between the suppressor and detector, serving to minimize the effect of pH on the conductometric base line and amplify divalent cation peak heights by a factor of about 5, thus greatly increasing the sensitivity of the technique. The major advantage of the method is the wide range of eluent pH which becomes available. Thus transition metal cations can be eluted in acidic solution without being exposed to a neutral or alkaline environment at any point in the system. Use of the ion chromatographic technique described for the analysis of Mg(2+) and Ca(2+) in pond water samples is described. The samples were analyzed both by ion chromatography using the 1 mM Ba (NO3)2 eluent at pH 4 with the post-column in line and by atomic absorption spectrometry. The results from the two techniques never differed by more than 3%. (Baker-FRC)

WATER HARDNESS DETERMINATION BY THE CATALYTIC POLAROGRAPHIC WAVE OF MAGNESIUM ION,
Foxboro Co., MA.
M. C. Cheney, D. J. Curran, and K.S. Fletcher, III.
Analytical Chemistry, Vol 52, No 6, p 942-945, May, 1980. 2 Fig, 1 Tab, 18 Ref.

Descriptors: *Water analysis, *Magnesium, Chemical analysis, *Hardness, Measuring instruments, Polarographic analysis, Chemical properties.

A water hardness measurement technique is presented which is based on the stoichiometric displacement of magnesium from its relatively weak EDTA complex by most divalent metal ions. Subsequent determination of free Mg(2+) using the catalytic wave that results when it is reduced at the dropping mercury electrode provides a substantial amplification effect. Though the relationship between observed catalytic current and concentration of Mg(2+) is linear over a relatively narrow range of concentration, the technique offers a rapid and sensitive method for determination of water hardness. Samples of tap water, well water, and an artificially prepared hard water containing 25.0 ppm Ca(2+) and 20.0 ppm Mg (2+) were analyzed by this method and by the standard EDTA titration method. Results were accurate to within 1% of the titration values and precision was on the order of 1%. (Baker-FRC)

DETERMINATION OF CHROMIUM SPECIATION IN NATURAL WATERS BY ELECTRODEPOSITION ON GRAPHITE TUBES FOR ELECTROTHERMAL ATOMIZATION,
Australian Atomic Energy Commission Research Establishment, Lucas Heights.
G. E. Batley, and J. P. Matousek.
Analytical Chemistry, Vol 52, No 11., p 1570-1574, September, 1980. 6 Fig, 1 Tab, 22 Ref.

Descriptors: *Natural waters, *Chromium, *Water analysis, Chemical analysis, Electrothermal atomization, Electrochemistry.

Studies of the electrodeposition-atomization technique and its potential for the analysis of chromium species in seawater are described. Matrix interferences can be overcome and preconcentration achieved by the electrodeposition of chromium with mercury onto pyrolytic graphite-coated tubular furnaces, using a flow-through assembly. At pH 4.7, using a desposition potential of -1.8 V vs. SCE, both Cr(VI) and Cr(III) are reduced and accumulated as metallic chromium. At the same pH, but at -0.3 V vs. SCE, only Cr(VI) is selectively reduced to Cr(III), which accumulates by adsorption. Using the labile-bound discrimination of the electrodeposition technique combined with an ultraviolet irradiation step, Cr(VI) was found to be dominant in the samples studied, with most Cr(VI) present as labile forms. ORGANIC MATRIX MODIFIERS FOR DIRECT GRAPHITE FURNACE ATOMIC ABSORPTION DETERMINATION OF CADMIUM IN SEAWATER,
National Research Council of Canada, Halifax (Nova Scotia). Atlantic Regional Lab.
R. Guevremont.
Analytical Chemistry, Vol 52, No 11, p 1574-1578, September, 1980. 3 Fig, 4 Tab, 17 Ref.

Descriptors: *Seawater, *Cadmium, Water analysis, Chemical analysis, Spectral analysis, Atomic absorption spectrometry, Reagent.

The application of citric acid, lactic acid, aspartic acid, histidine, and EDTA to direct graphite furnace analysis of cadmium in seawater is described. The agreement between analyses performed using the different reagents was very good. The application of EDTA gave results in good agreement with APDC/MIBK solvent extraction followed by graphite furnace atomic absorption and with ion exchange on Chelex-100 resin followed by isotope dilution spark source mass spectrometry. Citric acid appeared to be the most promising reagent used thus far. The sensitivity possible with this reagent is higher and the background interferences were small and easily controlled. The major difficulty with this reagent is the shortness of the atomic absorption signal. The lowest standard deviation in the measurement of cadmium in seawater was obtained using aspartic acid. In seawater this reagent had excellent sensitivity and low background absorbance. In deionized water, however, it did not promote low temperature atom production to the extent possible using citric acid or lactic acid. (Baker-FRC)

COMPARISON OF METHODS FOR THE DETERMINATION OF TRACE ELEMENTS IN SEAWATER,
National Research Council of Canada, Ottawa (Ontario). Div. of Chemistry.
R. E. Sturgeon, S. S. Berman, J. A. H. Desaulniers, A. P. Mykytiuk, and J. W. McLaren.
Analytical Chemistry, Vol 52, No 11, p 1585-1588, September, 1980. 3 Tab, 16 Ref.

Descriptors: *Seawater, *Chemical analysis, *Trace elements, Water analysis, Metals, Cadmium, Zinc, Lead, Iron, Manganese, Copper, Nickel, Cobalt, Chromium, Atomic absorption spectrometry, Emission spectroscopy, Ion exchange.

The analysis of coastal seawater for Cd, Zn, Pb, Fe, Mn, Cu, Ni, Co, and Cr was carried out using isotope dilution spark source mass spectrometry (IDSSMS), graphite-furnace atomic absorption spectrometry (GFAAS), and inductively coupled plasma emission spectrometry (ICPES) following trace metal separation-preconcentration using ion-exchange and chelation-solvent extraction, and direct analysis by GFAAS. Cu, Ni, Pb, Cr, and Co could not be measured by direct GFAAS in the stored seawater samples because of their inherently low concentrations and/or pronounced physicochemical matrix interference effects. Manganese

URBANA, IL. LIBRARY

could not be determined by ICPES using a 25-fold preconcentration of the trace elements, as their levels in such concentrates remain below values at which reliable analysis can be performed. Overall good agreement was obtained between the elemental values in relation to the method of analysis. The precision of replicate determination between methods for all elements is comparable. Complete analysis of each sample by all the methods indicated usually required about two months. The results of this study give confidence in the ability of the individual methods to give accurate analytical data and in the effectiveness of the standard addition approach in compensating for physicochemical interferences arising during sample preconcentration and instrumental analysis. (Baker-FRC)

ENTERIC VIRUSES IN RENOVATED WATER IN MANITOBA,
Cadham Provincial Lab., Winnipeg (Manitoba).
L. Sekla, W. Stackiw, C. Kay, and L. VanBuckenhout.
Canadian Journal of Microbiology, Vol 26, No 4, p 518-523, 1980. 4 Tab, 31 Ref.

Descriptors: *Viruses, *Wastewater renovation, Water reuse, Water shortage, Wastewater treatment, Drinking water, Potable water, Effluents, Rivers, Water analysis, *Manitoba, Canada.

This paper reports on procedures used in, and the findings obtained from, recovering enteric viruses from a Manitoban waterway system consisting of a sewage treatment plant, a river, and a water treatment plant. Both the liquid and the solid (sludge) components of sewage were sampled. The viruses isolated from raw sludge, sewage, final effluent, river water, and drinking water are listed. Of the 57 poliovirus isolates from sewage, 22 were tested and found to be vaccine strains. All three viruses isolated from the river were obtained from the same sample, collected at the middle of the river near the outlet of the sewage treatment plant in October of 1978. Thirteen of the isolates from drinking water were found on samples taken 2 days apart. The first 14 isolates found were confirmed as vaccine strains. This study has demonstrated the presence of enteric viruses in sewage and drinking waters, thus confirming the hypothesis that viruses can be recycled. The presence of enteric viruses in 61.8% of the sewage samples was expected. The presence of enteric viruses in 20.5% of the final sewage effluent samples was also expected. The recovery of enteric viruses from 6.75% of the drinking water samples is a matter of concern. All viruses so recovered were polioviruses, and thos tested were found to be vaccine strains, a sequel to the extensive immunization program carried out in Manitoba since 1962. (Baker-FRC)

MULTIELEMENT PRECONCENTRATION OF TRACE HEAVY METALS IN WATER BY COPRECIPITATION AND FLOTATION WITH INDIUM HYDROXIDE FOR INDUCTIVELY COUPLED PLASMA-ATOMIC EMISSION SPECTROMETRY,
Nagoya Univ. (Japan).
M. Miraide, T. Ito, M. Baba, H. Kawaguchi, and A. Mizuike.
Analytical Chemistry, Vol 52, No 6, p 804-807, May, 1980. 2 Fig, 4 Tab, 3 Ref.

Descriptors: *Heavy metals, *Water analysis, Measuring instruments, Chemical analysis, Chromium, Manganese, Nickel, Cobalt, Cadmium, Lead, Spectrometers, Spectral analysis, Analytical techniques.

Microgram quantities of Cr(III), Mn(II), Co, Ni, Cu(II), Cd, and Pb in 1200-ml samples were quantitatively coprecipitated with indium hydroxide at a pH of 9.5. After adding ethanolic solutions of sodium oleate and dodecyl sulfate, the precipitates are floated with numerous tiny nitrogen bubbles to the solution surface, and then collected in a small sampling tube. The procedure is simple and rapid, and suitable for operation at sampling spots. The heavy metals in the dissolved precipitates are determined by inductively coupled plasma-atomic emission spectrometry. The concentrations of the heavy metals are increased 240-fold, and those of alkali and alkaline earth metals in artificial seawater are reduced to 1/50-1/20 for sodium and potassium, and about 1/2 for magnesium, calcium, and strontium. Heavy metals at the low microgram/liter level in water or artificial seawater were simultaneously preconcentrated and determined by this procedure. The time required for preconcentration was about 40 minutes. (Baker-FRC)

DETERMINATION OF MOLYBDENUM IN SEA AND ESTUARINE WATER WITH BETA-NAPHTHOIN OXIME AND NEUTRON ACTIVATION,
Dalhousie University, Halifax (Nova Scotia). Dept. of Chemistry.
A. I. Kulathilake, and A. Chatt.
Analytical Chemistry, Vol 52, No 6, p 828-833, May, 1980. 1 Fig, 9 Tab, 53 Ref.

Descriptors: *Water analysis, *Molybdenum, Chemical analysis, Seawater, Neutron activation analysis, Estuaries, Trace elements, Heavy metals.

An analytical method for the determination of trace quantities of molybdenum in sea and estuarine water employing neutron activation analysis preceded by preconcentration of the element using beta-naphthoin oxime is presented. Radioactive tracers were used to investigate the various factors which can influence the sensitivity of the method. Concentrations of sodium, chlorine, and bromine in untreated seawater and cocrystallized product have been compared for evaluating the ability of beta-naphthoin oxime to reduce interferences from these three elements. Selectivity of beta-naphthoin oxime in preconcentrating molybdenum was studied using two diverse matrices, seawater and steel, which are known to contain several elements at drastically different concentrations. Molybdenum concentrations in samples of sea and estuarine water were determined with good precision and accuracy by this method. Beta-naphthoin oxime was found to be superior to alpha-benzoin oxime in selectively cocrystallizing molybdenum quantiatively from water. Detection limits were such that small amounts of molybdenum could be measured in the presence of large quantities of interfering elements. (Baker-FRC)

AMMONIA ELECTRODE WITH IMMOBILIZED NITRIFYING BACTERIA,
Akinomoto Co., Inc., Kawasaki (Japan). Central Research Lab.
M. Hikuma, T. Kubo, T. Yasuda, I. Karube, and S. Suzuki.
Analytical Chemistry, Vol 52, No 7, p 1020-1024, June, 1980. 7 Fig, 5 Tab, 11 Ref.

Descriptors: *Wastewater analysis, *Ammonia, Water analysis, Measuring instruments, Industrial wastes, Electrodes, Chemical analysis.

Nitrifying bacteria were immobilized by being entrapped between two membranes, a porous acetylcellulose membrane and the Teflon membrane of an oxygen electrode. This microbial sensor was then applied to the determination of ammonia in wastewaters. When a sample solution was pumped into the flow system of the sensor, the electrode current decreased to a steady state after 8 minutes. Measurement could be also made with a 3-minute pumping period with little loss of sensitivity. The calibration plot of the current difference vs. concentration of ammonia was linear up to 1.3 mg/liter. The sensor was applied to the determination of ammonia in wastewaters of a fermentation factory. The concentration of ammonia and the biological oxygen demand (BOD) of the sample solutions were determined by the distillation acidimetry and Japanese Industrial Standard methods, respectively. Good agreement was obtained between the ammonia concentration determined by the conventional method and that obtained by the microbial sensor. The relative difference betweeb the two methods was less than 6%. The results were not affected by organic compounds. The microbial sensor could be used for more than two weeks and 1400 assays. The electrode current difference decreased gradually, necessitating occasional recalibration of the electrode. (Baker-FRC)
W82-01099

DETERMINATION OF NICKEL BY DIFFERENTIAL PULSE POLAROGRAPHY AT A DROPPING MERCURY ELECTRODE,
Laurentian Univ., Sudbury (Ontario). Dept. of Chemistry.
C. J. Flora, and E. Nieboer.
Analytical Chemistry, Vol 52, No 7, p 1013-1020, June, 1980. 4 Fig, 5 Tab, 49 Ref.

Descriptors: *Water analysis, *Nickel, Metals, Chemical analysis, Polarographic analysis, Lakes, Drinking water, Potable water, Pollutant identification.

The use of differential pulse polarography (DPP) in the analysis of nickel was examined. The detection limit of the method of 2 ppb with a confidence interval of 95% and observed standard deviations of the same magnitude for the DMG-sensitized procedure are all comparable to those possible with modern electrothermal AA of nickel. Detection limits and precision are virtually limited by the ability to avoid contamination. The proposed DPP methods are well suited to the routine analysis of water and other aqueous samples. Especially advantageous is the flexibility to extend the analytical concentration range from ng/ml. The advent of the laboratory minicomputer should also lead to many innovations and improved performances with this method. In an analysis of Sudbury Lake and tap water, agreement between DPP and AA results are excellent for the July 7, 1978 data and somewhat less satisfactory for the data from the remaining time of experimentation. The DPP analysis requires no pretreatment of the water samples and is an extremely rapid, sensitive, reproducible, and convenient method conducting water analyses. The high contents of nickel found in Sudbury tap and lake water may be related to nickel emissions associated with local smelting and refining of the metal. (Baker-FRC)

5B. Sources Of Pollution

ANTHROPOGENIC TRACE ELEMENTS AND POLYCYCLIC AROMATIC HYDROCARBON LEVELS IN SEDIMENT CORES FROM TWO LAKES IN THE ADIRONDACK ACID LAKE REGION,
Department of Energy, NY. Environmental Measurements Lab.
M. Heit, Y. Tan, C. Klusek, and J. C. Burke.
Water, Air, and Soil Pollution, Vol 15, No 4, p 441-464, May, 1981. 2 Fig, 11 Tab, 37 Ref.

Descriptors: *Sediments, *Lakes, *Pollution load, Metals, Aromatic compounds, Hydrocarbons, *Acid rain, Acidic water, *Adirondacks, Sagamore Lake, Woods Lake, *New York, Sivter, Aluminum, Arsenic, Beryllium, Cadmium, Chromium, Copper, Mercury, Nickel, Lead, Tin, Vanadium, Zinc, Selenium, Thallium, Perylene.

The degree to which anthropogenic trace elements and polycyclic aromatic hydrocarbons have been deposited in remote lakes known to be affected by acid rainfall was investigated. The lakes investigated are located in the Adirondack State Park on the western slope of the Adirondack Mountains. Sagamore Lake is a brown water lake due to high levels of humic materials, while Woods Lake is generally clear. Sediment cores were taken from each of the lakes during March 1978. Several conclusions were reached. Except for perylene, the prime source of all parental PAHs measured and the majority of trace elements appears to be combustion. All combustion products had primarily an anthropogenic origin. Levels of all parental PAHs except perylene and levels of several of the metals significantly increased in the surface sediments of both lakes compared to their background concentrations. PAH concentrations in Woods Lake were quite high, approaching levels reported for more heavily

populated and industrialized areas. Metals were present at 3-4 times higher concentrations in Woods Lake than in Sagamore Lake. Metals and PAH levels decreased in concentration with depth to background levels in both lakes. This baseline depth corresponded to about 30 years ago. Lead has increased to the greatest extent of any of the metals considered relative to their baseline quality. Long distance atmospheric transport and region-wide deposition of anthropogenically derived elements and PAHs into these remote lakes appears to be more significant than input from local sources. (Baker-FRC)

RELATIONSHIPS BETWEEN SULFATE AND NITRATE ION CONCENTRATIONS AND RAINFALL PH FOR USE IN MODELING APPLICATIONS,
Battelle Pacific Northwest Lab., Richland, WA. Atmospheric Sciences Dept.
D. J. McNaughton.
Atmospheric Environment, Vol 15, No 6, p 1075-1079, 1981. 4 Fig, 2 Tab, 8 Ref.

Descriptors: *Acid rain, *Sulfates, *Nitrates, Mathematical modeling, Hydrogen ion concentration, Acidity, Air pollution effects, Anions, Rainfall, Water pollution sources.

Precipitation chemistry data for the northeastern United States were analyzed to test relationships between anthropogenic sulfate and nitrate ion contributions and rainfall pH. The data set incorporated all observations, with complete measurements of all three ion concentrations being collected from September 1976 through December 1979. A relationship was found between sulfates and nitrates and rainfall acidity expressed in terms of pH, and this relationship can be applied to deposition predictions to predict pH from regional air pollutant transport models. Variance in the pH versus ion relationships can be explained by the sulfate ion concentration alone. Thus, rainfall acidity patterns could be approximated by sulfate deposition patterns alone in cases where relative levels of nitrate ions and sulfate ions in the atmosphere are the same as those that influence precipitation. The analysis was based on the assumption that the predominant anions are anthropogenic, and this assumption could lead to an overprediction of rainfall acidity. (Small-FRC)

THE BREAKDOWN OF POULTRY MANURE AGGREGATES BY RAINFALL IMPACT,
Science and Education Administration, Ithaca, NY.
R. E. Muck, and D. C. Ludington.
Journal of Environmental Quality, Vol 9, No 1, p 61-65, January-March, 1980. 6 Fig, 3 Tab, 12 Ref.

Descriptors: *Manure, *Rainfall impact, Rainfall rate, Land disposal, Simulated rainfall, *Poultry, Nitrogen, Phosphorus, *Leaching, Kinetic energy, Poultry manure.

The effects of rainfall characteristics on the breakdown of dry poultry manure aggregates were investigated, and the effects of aggregate breakdown on the leaching of N and P from poultry manure were demonstrated. Simulated rainfall was used to determine the effects of rainfall intensity, duration, drop velocity, and drop size. Aggregate breakdown was an exponential function of rainfall amount for a constant drop velocity and size. Rainfall energy and momentum both explained the aggregate breakdown results for a constant drop size. As drop size increased, aggregate breakdown seemed to increase, but these results were not statistically significant. Aggregate breakdown caused increases in the leaching of nitrogen and phosphorus from the manure. With a 4 hr, 5.08 cm/hr simulated rainfall, aggregate breakdown accounted for a 70% increase in leaching losses from the manure. Thus, the type of crop cover on which manure is spread may affect nutrient losses due to rainfall. For example, hay would intercept the rainfall before it hit the manure and thus would reduce aggregate breakdown by rainfall. (Small-FRC)

DYE-SENSITIZED PHOTOOXIDATION OF BROMACIL IN WATER,
Volcani Inst. of Agricultural Research, Bet-Dagan (Israel). Div. of Soil Residues Chemistry.
A. J. Acher, and S. Saltzman.
Journal of Environmental Quality, Vol 9, No 2, p 190-194, April-June, 1980. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Bromacil, *Degradation, *Dyes, Pesticide residues, *Herbicides, Photodegradation, Chemical reactions, Solar radiation, Irradiation, *Fate of pollutants.

To study its fate in aquatic systems, the herbicide bromacil (3-sec-butyl-5-bromo-6-methyl uracil) in aqueous solution (250 ppm) was exposed to direct solar radiation in the presence of dye sensitizers at appropriate pH. The herbicide rapidly and completely photodegraded via a debromination mechanism to 3-sec-butyl-2-acetyl-2-hydroxy hydantoin, the major product (97-98%), and the 5,5'-dimer of 3-sec-butyl-6-methyl uracil, a minor product (1-2%). Unidentified polar compounds were formed upon continued degradation. The most effective dye sensitizers were riboflavin (10 ppm) and methylene blue (2-5 ppm). Less effective sensitizers were rose bengal (5 ppm), humic acids (20 ppm), and chlorophyll (20 ppm). The reaction proceeded more rapidly at alkaline pH. With sensitizers and a reaction time of 30 min, no degradation occurred at less than pH 5, 10% at pH 7, 20% at pH 8, and 80% at pH 10. The effects of suspended solids, often found in natural waters, were tested. An anion exchange resin partially inhibited degradation, and bentonite strongly inhibited degradation. Under optimal conditions (effective sensitizer, high pH, no suspended solids) photooxidation to the intermediate products was complete within 1 hour. (Cassar-FRC)

ACID RAIN AT KENNEDY SPACE CENTER, FLORIDA: RECENT OBSERVATIONS,
University of Central Florida, Orlando. Dept. of Chemistry.
B. C. Madsen.
Atmospheric Environment, Vol 15, No 5, p 853-862, May, 1981. 7 Fig, 6 Tab, 15 Ref.

Descriptors: *Acid rain, *Kennedy Space Center, *Florida, Rainfall, Air pollution, Fallout, Water pollution sources, Hydrochloric acid, Sulfuric acid, Nitric acid.

Precipitation samples were collected in automated samplers designed to prevent both dry deposition and evaporation. Determinations of major cation and anion concentrations were made within 10 days after sample collection. All sampling sites were on or near the Kennedy Space Center complex in Florida. In general, summertime acidity was greater than during other times of the year. Maximum free acidity was observed during July in both 1978 and 1979. The July rainfall accounted for 21 and 10% of the total amounts received during the respective years. Lowest acidities were noted in November 1977 and April 1979. No pattern was noted when rain composition from a specific month during the first year of the study was compared to the identical time in the following year. The presence of sulfate ion can be attributed primarily to non-marine sources. Monthly and annual deposition of components which will be important if changes in rain composition occur due to future SRM launches are presented. Free acidity, nitrate ion and excess sulfate ion deposition account for the present acid loading, while chloride ion deposition reflects the influence of the marine environment. Monthly weighted average chloride ion concentrations ranged from 20 to 240 micromole/liter. The chloride: sodium ion ratio was slightly lower than that present in sea water. (Baker-FRC)

TRACE ELEMENT CONCENTRATIONS OVER MIDLAKE MICHIGAN AS A FUNCTION OF METEOROLOGY AND SOURCE REGION,
Governors State Univ., Park Forest South, IL. Coll. of Environmental and Applied Sciences.
H. Sievering, M. Dave, D. Dolske, and P. McCoy.
Atmospheric Environment, Vol 14, No 1, p 39-53, January, 1980. 7 Fig, 12 Tab, 21 Ref.

Descriptors: *Trace elements, *Air pollution, *Aerosols, Heavy metals, Metals, Lakes, *Lake Michigan, Water pollution sources, Path of pollutants, Wind, Air-water interfaces.

Aerosol samples were collected during May-September 1977 over southern Lake Michigan. This location, 87 degrees west and 42 degrees north, is in midlake, 40 to 100 km removed from any shoreline aerosol sources. The samples were analyzed for Pb, Zn, Mn, Mo, Fe, Ti, Al, Ca, and Mg. Micro- and meso-meteorological conditions were recorded. Several general conclusions were derived. Midlake metal concentration variabilities are linearly independent of wind speed and strongly and directly dependent on temperature stability of the surface layer, defined as the lowest few meters of air above the lake surface. Midlake mass concentration variability is more dependent on fine particulate aerosols with high Pb, Zn, and Mn content than on the coarse particulate fraction. Temperature stability of the surface air layer is more important than sedimentation and aerosol aging in terms of aerosol concentration variability within that layer. Midlake metal concentrations are more dependent on nearshore sources than on long range transport. The largest amount of Pb (95%), Zn and Mn (75%), and Fe (over 50%) present in the midlake atmospheric surface layer is probably anthropogenic in origin. (Cassar-FRC)

GROUNDWATER CONTAMINANT TRANSPORT WITH ADSORPTION AND ION EXCHANGE CHEMISTRY: METHOD OF CHARACTERISTICS FOR THE CASE WITHOUT DISPERSION,
Texas Univ. at Austin. Dept. of Civil Engineering.
R. J. Charbeneau.
Water Resources Research, Vol 17, No 3, p 705-713, June, 1981. 6 Fig, 2 Tab, 12 Ref.

Descriptors: *Solute transport, *Adsorption, *Ion exchange, *Leaching, Ion transport, Groundwater movement, Uranium, Mining engineering, Path of pollutants, Ammonia, Organic compounds.

Contaminant transport involves not only the movement of a pollutant away from a waste disposal site or the fate of constituents in recharge water, but also site restoration problems caused by emerging technologies such as in situ leach mining for uranium and in situ gasification of lignite. This paper concerns adsorption and ion exchange reactions in the absence of dispersion. The method of characteristics is used to formulate the solution for any adsorption isotherm and an arbitrary number of exchanging cations. It is applicable to linear flow systems and to nonlinear systems along streamlines in a nonuniform field. With 2 exchanging cations the complete solution may be obtained by graphical means; when there are more than 2, a computer is required to solve the problem. The first example illustrates migration of organics using the nonlinear Freundlich isotherm for adsorption of organics on lignite. The second concerns the volume of water required to restore a uranium mining site by sweeping out residual ammonia and other contaminants. (Cassar-FRC)

MODELING OF PROCESSES OF DECOMPOSITION OF ORGANIC MATTER IN BOTTOM SEDIMENTS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
Ya. L. Fuksman.
Water Resources (English Translation), Vol 7, No 5, p 442-450, September/October, 1980. 6 Fig, 8 Ref. Translated from Vodnye Resursy, No 5, p 118-129, September/October, 1980.

Descriptors: *Mathematical models, *Decomposing organic matter, *Bottom sediments, Sediments, Organic matter, Decomposition, Mathematical equations, Mineralization, Fate of pollutants.

Although the decomposition of organic substances directly affects water quality, the mathematical description of this process is currently accomplished using rather simple models interpreting the general character of phenomena observed during the decomposition process. This paper discusses a more detailed mathematical model of biochemical processes of mineralization of organic matter with respect to bottom sediments. The systems of differential equations presented were developed on the basis of the energy balance in the heterotrophic population of bacteria. Nearly all of the parameters-constants used in the model have a definite thermodynamic or physiological significance. A flow of particles of detritus is produced by the dying phytoplankton. The amount of detritus is expressed by the weight of some biogenic element in the detritus, the cycle of which in the water body is being modeled. The biomasses of both aerobic and anaerobic bacteria are also phase variables in the model. Systems of differential equations for modeling anaerobic bacteria in an oxygen-free regime, anaerobic populations in the presence of oxygen, and populations of aerobic bacteria in the absence of anaerobic bacteria are presented. A model of the dynamics of an ecosystem with two populations is then developed which is composed of the model for the dynamics of the anaerobic population in the presence of oxygen and the model for the dynamics for the population of aerobes. TRACE ELEMENT INPUTS FROM A COAL BURNING POWER PLANT TO ADJACENT TERRESTRIAL AND AQUATIC ENVIRONMENTS,
Savannah River Ecology Lab., Aiken, SC.
D. W. Evans, J. G. Wiener, and J. H. Horton.
Journal of the Air Pollution Control Association, Vol 30, No 5, p 567-573, May, 1980. 4 Fig, 4 Tab, 25 Ref.

Descriptors: *Powerplants, *Water pollution, *Trace elements, Coal, Plumes, Coal fuel, Fallout, Air pollution, Rainfall, Fly ash.

Levels of trace elements derived from coal ash were investigated in terrestrial and aquatic samples near an 83 MW coal burning power plant. Comparisons were made between the trace elements arising through aerial deposition during 23 years prior to the installation of electrostatic precipitators and aquatic inputs from ash disposal basins after installation. A guassian plume model was used to predict deposition patterns of 29 trace elements in coal ash around the power plant. Detectable increases were noted in Sr, As, Sb, and Be in surface soils within 3 km of the power plant. Concentrations measured in surface soils were largely consistent with the predictions. Measurements of aerial deposition of Cd, Pb, Cu, and Mn at a site 5.5 km distant were similar to those in other rural areas and indicated that little of the measured Cd, Cu, Mn, or Pb was derived from fly ash. Concentrations of 12 heavy metals in effluents from the basin receiving ash were comparable to those predicted in rainfall deposited nearest the plant. It was concluded that at other coal combustion facilities, basin disposal could be a more serious contamination threat to aquatic environments than aerial dispersal of ash. (Baker-FRC)

RESIDUES OF NONYLPHENOL IN SPRUCE FOLIAGE, FOREST SOIL, STREAM WATER AND SEDIMENT AFTER ITS AERIAL APPLICATION,
Forest Pest Management Inst., Sault Ste Marie (Ontario).
K. M. S. Sundaram, S. Szeto, R. Hindle, and D. MacTavish.
Journal of Environmental Science and Health, Part B, Vol 15, No 4, p 403-419, 1980. 1 Fig, 3 Tab, 9 Ref.

Descriptors: *Phenolic pesticides, *Pesticide residues, *Stream pollution, Insecticides, Water pollution, Spruce trees, Conifers, Trees, Forest soils, Sediments, Nonylphenol.

The residues of nonylphenol, a major component of the Matacil (aminocarb) formulation, were measured in a variety of natural features following aerial application of a mixture of this chemical and insecticide diluent 585 at a rate of 0.47 liters per hectare to a mixed coniferous forest in Ontario. Nonylphenol residues were found in water from the forest stream one hour after application of the insecticide to the forest and up to five days after application. The highest concentration, 9.1 ppb, which was detected one hour after spraying, decreased to trace levels of less than 2.0 ppb after 6 hours, indicating a half-life of about 2.5 hours. Water samples taken from a stagnant area of the stream showed concentrations of 1,100 ppb 4 hours after spraying, decreasing to 110 ppb in the next 2 hours, to 12 ppb within 24 hours, and to less than 1.0 ppb after 3 days. Dilution by water flow probably accounts for most of the rapid dissipation of nonylphenol residues in the stream water, while surface evaporation and co-distribution may also have been contributing factors. Residues in white spruce foliage decreased from 18.90 ppm 1 hour after spraying to about 11.34 ppm after 3 hours and to less than 0.20 ppm after 62 days. Analyses of forest soil samples collected after spraying resulted in no detections of residues. Trace levels of nonylphenol were found in only one sediment sample collected 4 hours after spraying. These data indicate that very little residue would be present in forest soil and that residues in foliage, stream water, and sediment would be non-persistent following application of nonylphenol at a rate equivalent to the seasonal allowable maximum. ESTIMATION OF THE SALT BURDEN OF IRRIGATION DRAINAGE WATERS,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
W. A. Jury, and P. F. Pratt.
Journal of Environmental Quality, Vol 9, No 1, p 141-146, January-March, 1980. 5 Fig, 5 Tab, 10 Ref.

Descriptors: *Mathematical models, *Salts, *Irrigation water, Irrigation effects, Water pollution sources, Mathematical studies, Water analysis, Path of pollutants.

The effectiveness of several different models for the prediction of important interactions which govern the salt movement process through soil was evaluated. The three models used to predict salt concentration and mass emissions below irrigated fields included a proportional model, a steady-state model, and a dynamic model. The proportional model overestimated the salt burden for waters which tend to precipitate calcium salts and underestimated the salt burden of waters which tend to dissolve soil CaCO3. The steady-state model predicted a greater tendency toward mineral dissolution than occurs when ion exchange is considered, but it calculated a more accurate salt balance than did the proportional model. The proportional model characterized irrigation management in terms of an average ratio of drainage volume to irrigation volume (leaching fraction, LF). When the saline irrigation water had LF=0.1, the steady-state model mass emission prediction was 22% less and the transient model prediction was 36% less than the estimates of the proportional model. When the irrigation water was of high quality (LF=0.4), the predictions of the two models were 198 and 201% higher, respectively, than the predictions of the proportional model. (Small-FRC)

DISTRIBUTION OF SILVEX, 2,4-D, AND TCDD APPLIED TO TURF IN CHAMBERS AND FIELD PLOTS,
Science and Education Administration, Beltsville, MD. Pesticide Degradation Lab.
R. G. Nash, and M. L. Beall, Jr.
Journal of Agricultural and Food Chemistry, Vol 28, No 3, p 614-623, May/June, 1980. 3 Fig, 10 Tab, 18 Ref.

Descriptors: *Leachates, *Organic compounds, Leaching, Infiltration, Percolation, *Path of pollutants, *Agricultural chemicals, Pesticides, Herbicides, Silvex, 2,4-D, Dioxins, TCDD, Residues, Water pollution.

The fate of 2,4-D, silvex, and TCDD applied to bluegrass turf was examined in four components, soil, grass, water, and air, of microagroecosystem chambers. Concentrations employed were as follows: 1.3 kg of granular 2,4-D per hectare, 2.8 kg granular and 2.0 kg emulsifiable silvex per hectare. A high-activity radiolabeled preparation of the possible toxic trace contaminant of silvex, TCDD, was added. Residue half-times for silvex on soil were 35 days for both formulations and 10 days for granular 2,4-D. TCDD concentrations in leachate water were less than 10 to the minus 16th power and 10 to the minus 13th power g/g water after silvex applications containing 44 ppb and 7.5 ppm TCDD, respectively. Silvex and 2,4-D concentrations were in the microgram/liter range as leachates and decreased with time. TCDD concentrations were less than 0.1 pg/liter. The TCDD concentration in the leachate seemed to increase with time, peaked on day 126, and then decreased to less than 10 pg/liter by day 275. The half-life values for leachate water, with high correlation coefficients, were about 10 days for both formulations of silvex and 6.5 days for the granular 2,4-D. After day 126, the half-life values for TCDD were 65 and 57 days for the emulsifiable concentrate and granular formulations, respectively. (Baker-FRC)

RESIDUES OF ISOBORNYL THIOCYANOACETATE (THANITE) AND A METABOLITE IN FISH AND TREATED PONDS,
National Fishery Research Lab., La Crosse, WI.
J. L. Allen, J. B. Sills, V. K. Dawson, and R. T. Amel.
Journal of Agricultural and Food Chemistry, Vol 29, No 3, p 634-636, 1981. 3 Tab, 9 Ref.

Descriptors: *Ponds, *Fish, *Insecticides, Carp, Bass, Metabolites, Sublethal effects, Thanite, Pesticide residues, Fate of pollutants.

The insecticide isobornyl thiocyanoacetate (Thanite) induces a surfacing response in fish, which may permit live collection of fish. However, there are no data on residues of the insecticide in fish exposed to the chemical nor on the persistence of Thanite in the aquatic environment. Only a trace of the parent compound was found in carp and largemouth bass exposed to Thanite at 1 mg/liter in the laboratory. A metabolite, isobornyl alpha-(methylthio)-acetate, was isolated and identified by gas chromatography-mass spectroscopy, and a reference standard for the metabolite was synthesized. Residues of the metabolite were found in the muscle tissue of largemouth bass and in the muscle tissue, blood plasma, and bile of carp within one hour after exposure to Thanite. Residues of the metabolite decreased to undetectable levels within 24 hours of withdrawal from water containing Thanite for the bass and within 48 hours for the carp. Residues of Thanite were detectable in water and soil samples from experimental ponds up to 14 days after treatment at 0.4 mg/liter, but not at 21 days after treatment, while algae samples contained detectable levels of Thanite in the 21-day samples but not at 28 days. The metabolite found in the bass and carp was not found in samples of water, soil, or algae. The results demonstrate that Thanite is rapidly metabolized and eliminated by fish and does not persist in a pond environment beyond 3 weeks. (Carroll-FRC)

WATER-TO-AIR FRACTIONATION OF BACTERIA,

Florida State Univ., Tallahassee. Oceanography Dept.
T. W. Hejkal, P. A. LaRock, and J. W. Winchester.
Applied and Environmental Microbiology, Vol 39, No 2, p 335-338, February, 1980. 4 Fig, 17 Ref.

Descriptors: *Bacteria, *Air-water interfaces, Interfaces, Escherichia coli, Serratia marinorubra, Micrococcus euryhalis, Pseudomonas bathycetes, Bacillus subtilis, Water treatment facilities, Wastewater treatment, Spray irrigation, Human disease, *Path of pollutants.

An attempt was made to determine the quantitative differences among several bacterial species in their abilities to be ejected into the atmosphere by bubbles rising through water and bursting at the air-water interface. Three species of marine bacteria, Serratia marinorubra, Pseudomonas bathycetes, and Micrococcus euryhalis, were tested for their ability to be aerosolized. Bubbles were generated in suspensions of mixed bacterial cultures, and the concentration was measured for each species in the top jet drop ejected. This concentration, divided by the concentration in the bulk menstruum, is the concentration factor (CF). Bubbles were generated 2 cm below the liquid surface, and jet drops with diameters from 34 to 136 micrometers were studied. S. marinorubra and M. euryhalis had CFs which were generally 10 to 100 times greater than those of Escherichia coli, P. bathycetes, and spores of Bacillus subtilis. P. bathycetes never had a CF significantly greater than 1 at any drop size, and spores of B. subtilis had a maximum CF of 4. E. coli had a maximum CF of 6 to 1- or 2-day old cultures, but this increased to 80 when a 5 day old culture was used. This change in the CF with age of the cells indicates that composition of the cell may be a factor influencing its ability to concentrate in jet drops. (Baker-FRC)

UTILIZATION OF DICHLOROMETHANE BY SUSPENDED AND FIXED-FILM BACTERIA,
Stanford Univ., CA. Dept. of Civil Engineering.
B. E. Rittmann, and P. L. McCarty.
Applied and Environmental Microbiology, Vol 39, No 6, p 1225-1226, June, 1980. 2 Fig, 8 Ref.

Descriptors: *Bacteria, *Effluents, *Dichloromethane, Biodegradation, Industrial wastes, Wastewater, Growth, Organic compounds, Fate of pollutants.

The biodegradation of dichloromethane, a commonly used solvent ubiquitous in aqueous environments, is described and evidence that the chemical will support bacterial growth is offered. Bacterial cultures were enriched from a seed of primary sewage effluent over a 12 month period. Several enrichment cultures, having different bacterial densities, were developed. It was noted that culture turbidity changes and dichloromethane utilization were not significant if bicarbonate was omitted from the mineral medium. The enriched bacteria were predominately gram-negative, motile rods. Batch, suspended-growth and biofilm experiments were performed to demonstrate dichloromethane utilization. The biological utilization of dichloromethane at 1-25 mg/liter by suspended bacteria was readily apparent. Since neither carbon dioxide evolution nor intermediates were measured, it was not possible to state whether dichloromethane was completely mineralized or by what pathway it was metabolized. Even so the study shows that dichloromethane can be used as an energy source without serving as a cometabolite. Although not conclusive, the fact that suspended growth was reduced when bicarbonate was omitted from the mineral medium suggest that the autotrophic pathway was used. (Baker-FRC)

MOVEMENT OF ENDOTOXIN THROUGH SOIL COLUMNS,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
S. M. Goyal, C. P. Gerba, and J. C. Lance.
Applied and Environmental Microbiology, Vol 39, No 3, p 544-547, March, 1980. 1 Fig, 2 Tab, 18 Ref.

Descriptors: *Endotoxin, *Groundwater pollution, Rainfall, Percolation, *Land disposal, *Bacteria, Wastewater disposal, Waste disposal, Adsorption, Toxins, Soil contamination.

The possible removal of endotoxin during land treatment and the chance that endotoxin can reach groundwater after land application of wastewater were investigated. The movement of endotoxin through soil columns was studied under laboratory conditions. A 10 cm diameter polyvinyl chloride pipe was packed with loamy sand from the dry Salt River bed located near Phoenix, Arizona. Either 100 or 250-cm long soil columns were employed. While it was determined that endotoxin is removed by the soil, it was noted that endotoxin-containing sewage must travel longer distances than virus-containing sewage before any appreciable removal occurs. Free endotoxin is refractory to adsorption by granulated activated-carbon columns, whereas 83% of bound endotoxin is removed by passage through two granulated activated-carbon columns in series. Thus, there is a potential for some endotoxin contamination of groundwater if the aquifer is shallow. When a simulated rainfall was applied to the columns in which the endotoxin had been adsorbed, the endotoxin concentration moved through the soil as a concentrated band. Thus it appears that rainwater can desorb endotoxin from soil and that travel of endotoxin to groundwater is a distinct possibility. In field studies, two land treatment sites were sampled to compare the amount of endotoxin in the sewage being applied and that present in groundwater samples. At Lubbock, Texas, 600 to 6000 ng of endotoxin per ml was found in the sewage, and 0.6 to 480 ng/ml in the groundwater. At Fort Devens, 300 ng of endotoxin per ml was in the sewage, and 0.3 to 30 ng/ml in the groundwater. (Baker-FRC)

DYNAMICS OF SELENIUM IN MERCURY-CONTAMINATED EXPERIMENTAL FRESHWATER ECOSYSTEMS,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
J. W. M. Rudd, M. A. Turner, B. E. Townsend, A. Swick, and A. Furutani.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 5, p 848-857, May, 1980. 8 Fig, 3 Tab, 32 Ref.

Descriptors: *Path of pollutants, *Aquatic animals, *Ecosystems, *Selenium, *Mercury, Bioaccumulation, Fate of pollutants, Herbicides, Fish toxins, Heavy metals, Water pollution effects, Water pollution sources, Lakes, Sulfate, Benthos, Crayfish, Bottom sediments.

The movement of selenium (Se) and mercury (Hg) through experimental aquatic ecosystems in a lake contaminated with mercury (Hg) was studied. Stable Se or sulfate water concentrations were increased while aquatic herbicides (Velpar or terbutryne) were added to the model system. Part of the water column was isolated from contact with the sediments. Radioactively labeled Se and Hg did not move simultaneously through the ecosystem either geochemically or biologically. Se was rapidly bioaccumulated in fish, crayfish, and haptobenthos, an effect which was enhanced by increased sulfate levels in the absence of exposure to bottom sediments and decreased by aquatic herbicides. Se levels of 0.1 mg/l did not affect Hg movement out of the water column, but stabilized Hg movement among different compartments of the water column. Hg bioaccumulation by fish, crayfish and haptobenthos was inhibited by elevated Se levels. Se toxicity to several aquatic species was investigated. The possible use of Se as an ameliorating agent for freshwater systems polluted by heavy metals is considered. (Geiger-FRC)

BIODEGRADABILITY OF HALOGEN-SUBSTITUTED DIPHENYLMETHANES,
Monsanto Co., St. Louis, MO.
V. W. Saeger, and Q. E. Thompson.
Environmental Science and Technology, Vol 14, No 6, p 705-709, June, 1980. 2 Tab, 18 Ref.

Descriptors: *Biodegradation, *Organic compounds, Molecular structure, Hydrocarbons, Halogens, *Diphenylmethanes, Activated sludge, River water, Microorganisms, Rivers.

Primary and ultimate biodegradation test procedures were used to determine the biodegradability of 32 halogenated diphenylmethanes exposed to activated sludge and river water microorganisms. Generally, diphenylmethanes having one unsubstituted phenyl ring exhibited high primary degradation rates. Those substituted on both rings were slow to degrade. Ultimate biodegradation measurements on materials with high primary degradation rates indicate that the cleavage rate of the second phenyl ring decreases, in general, with increasing levels of substitution on the ring. The data point out, however, the inherent difficulties in predicting whether a specific synthetic molecule will be biodegradable. In keeping with other facets of biological behavior, minor changes in structure can lead to drastic changes in biodegradability. (Baker-FRC)

THE NONFUEL MINERALS INDUSTRY: REGULATORY IMPACTS,
Mitre Corp., McLean, VA. METREK Div.
A. Hershaft, and W. Lacy.
Environmental Science and Technology, Vol 14, No 4, p 404-408, 410-412, April, 1980. 6 Tab.

Descriptors: *Mineral industry, *Metal-finishing wastes, Metallurgy, Industrial plants, Industrial wastes, Effluents, Mine wastes, Mine drainage, Drainage, Water quality, Regulations, Standards.

Water pollutants are generated at every step of metal mining and processing. Runoff from exposed ore bodies and overburden and tailing piles carries suspended solids, acid sulfate, heavy metals, and other dissolved salts. Some of these pollutants find their way into the groundwater. The slurry contains additional suspended solids, as well as chemicals used in the ore concentration process. Smelting and refining effluents contain heavy metals and other substances, sometimes ammonia, cyanides, nitrates, oil and grease, and phenols introduced with coke, as well as fluorides added as a fluxing agent. Runoff can be minimized and directed to tailing ponds of containment lagoons. Percolation to the groundwater can be controlled by lining the bottom of the pond with clay, paving material, or an impermeable plastic or rubber membrane. Public concern has generated laws in recent years to assist in the management of mining and processing wastes. Pollution from these operations can adversely affect eight types of water uses: municipal supply, industrial supply, agricultural supply, commercial fishing, wildlife preservation, recreation, navigation, and aesthetic enjoyment. Assessing the benefits to these water uses derived from the regulatory statements issued by the federal and state governments is difficult. However, there is impressive evidence of water quality improvement attributable to pollution control regulations. (Baker-FRC)

COAL TAR COATINGS OF STORAGE TANKS, A SOURCE OF CONTAMINATION OF THE POTABLE WATER SUPPLY,
New York State Dept. of Health, Albany. Div. of Lab. and Research.
K. Alben.
Environmental Science and Technology, Vol 14, No 4, p 468-470, April, 1980. 1 Fig, 3 Tab, 10 Ref.

Descriptors: *Storage tanks, *Coatings, Linings, Leaching, Leachates, Water storage, Water tanks, Storage, Hydrocarbons, Water quality, Water pollution sources, *Coal tar coatings, Health hazards.

Forty-liter field samples were collected in duplicate at the inlet and outlet of a 12,000 gallon

storage tank which had been given an interior coating of coal tar five years earlier. Similarly, 40-liter laboratory samples were prepared from tap water exposed to test panels coated with the same coal tar as used on the storage tank. Results obtained from GC-MS analysis of the storage tank samples indicated that concentrations of specific polycyclic aromatic hydrocarbons increased 5 to 30 times over the concentrations of the same chemicals found in the influent to the tanks. Concentrations in micrograms/liter in the influent and effluent respectively for the following compounds were: naphthalene, 0.004 and 0.025; fluorene, 0.001 and 0.021; phenanthrene + anthracene, 0.019 and 0.210; fluoranthene, 0.003 and 0.081; and pyrene 0.002 and 0.071. It was concluded that polycyclic aromatic hydrocarbons can leach from commercial coal tar coatings of storage tanks into the water supply. One of the compounds, fluoranthene, is among the six polycyclic aromatic hydrocarbons designated by the World Health Organization as possessing a health hazard when drinking water is contaminated with it. The levels of each of the chemicals detected are considered to be significant. (Baker-FRC)

AROMATIC AMINES IN AND NEAR THE BUFFALO RIVER,
Indiana Univ. at Bloomington. School of Public and Environmental Affairs.
C. R. Nelson, and R. A. Hites.
Environmental Science and Technology, Vol 14, No 9, p 1147-1149, 1980. 3 Fig, 2 Tab, 7 Ref.

Descriptors: *Dye industry wastes, *Water pollution sources, Industrial wastes, Rivers, *Buffalo River, Fish, Fish diseases, Leaching, New York.

The identification of the 2-propanol-extractable, basic organic compounds present in soil and river sediment obtained near a dye manufacturing plant is described. The environmental implications of this identification are discussed. Sediment samples were collected in midchannel by an Eckman dredge during June of 1979. Soil samples were collected in 1978. The following aromatic amines were found in the sediment samples from the Buffalo River: 4,4'-bis(dimethylamino)biphenyl, 4-(dimethylamino)benzophenone, bis(4-dimethylaminophenyl)methane, bis-(4-dimethylaminophenyl)phenylmethane, 1-naphthylamine, and N-ethyl-N-phenylbenzylamine. Most of the compounds detected are either starting materials, intermediates, byproducts, or products associated with the commercial synthesis of two dyes: malachite green and crystal violet. The remaining compounds were either other products of the dyestuff plant or common industrial chemicals. The findings of so many chemicals in the soil samples suggests that the site was used as a chemical dump by the dyestuff manufacturer, and it is further suggested that the chemicals entered the Buffalo River by leaching from the dump site. Fish in the river have been exposed to these compounds by direct contact with contaminated sediment, and their numerous tumors may have resulted from this exposure. (Baker-FRC)

GROUNDWATER LEACHING OF ORGANIC POLLUTANTS FROM IN SITU RETORTED OIL SHALE. A MASS TRANSFER ANALYSIS,
California Univ., Berkeley. Dept. of Civil Engineering.
G. L. Amy, A. L. Hines, J. F. Thomas, and R. E. Selleck.
Environmental Science and Technology, Vol 14, No 7, p 831-835, July, 1980. 4 Fig, 2 Tab, 18 Ref.

Descriptors: *Groundwater, *Leaching, *Oil shale, Groundwater pollution, Organic compounds, Mass transfer, Diffusion coefficient.

A mass transfer analysis of laboratory data was conducted to evaluate the potential degradation of groundwater quality by organic pollutants leached from in situ retorted oil shale. Two unique samples of in situ retorted oil shale were investigated in a series of laboratory experiments. Results of the experiments were subjected to a mass transfer analysis to determine the rate-limiting step involved in the leaching of organic pollutants by groundwater. This mass transfer analysis suggested that, for one of the samples, internal diffusion through the porous infrastructure of retorted oil shale particles is the rate controlling mass transfer step. For the other sample, no single rate controlling step was conclusively identified, although it appeared that internal diffusion was important in the overall leaching phenomenon. Since internal diffusion is an extremely slow mass transfer process, it is anticipated that low, relatively constant levels of organic pollutants will appear in groundwater and persist for long periods of time. This implies that there may be a chronic, long-term groundwater pollution problem in areas of future in situ oil shale development. (Baker-FRC)

TRACE METAL CATALYSIS IN AQUATIC ENVIRONMENTS,
California Inst. of Tech., Pasadena. W. M. Keck Labs.
M. R. Hoffman.
Environmental Science and Technology, Vol 14, No 9, p 1061-1066, September, 1980. 4 Fig, 1 Tab, 52 Ref.

Descriptors: *Catalysts, *Trace metals, *Water pollution control, *Chemical reactions, Heavy metals, Aquatic environment, Oxidation, Reduction, Sulfur compounds, Suspended matter.

The possible roles that trace metals may play in the catalysis of aquatic reactions are exlored, and the kinetic and mechanistic aspects of hydrolysis, redox, and autoxidation reactions are explained. The applicability of certain catalytic reactions for pollution control is considered. It is noted that transition metals and associated complexes may prove useful from a commercial standpoint for improved pollution control systems. The catalyzed autoxidation of hydrogen sulfide and sulfur dioxide and other reduced sulfur compounds in the presence of homogeneous or heterogeneous organometallic complexes may provide convenient and economical methods for sulfur pollution control. The principal products of the metal phthalocyanine-catalyzed autoxidation of hydrogen sulfide and mercaptans in sour refinery distillates are reported to be colloidal sulfur, polythionates, and sulfate. Conceivably, similar catalytic systems could be used for the autoxidation of selected organic pollutants for industrial wastewater treatment. (Baker-FRC)

KEPONE IN THE JAMES RIVER,
Virginia Inst. of Marine Sciences, Gloucester Point.
R. J. Huggett, and M. E. Bender.
Environmental Science and Technology, Vol 14, No 8, p 918-923, August, 1980. 3 Fig, 3 Tab, 16 Ref.

Descriptors: *Rivers, *Pesticides, *Kepone, *James River, *Virginia, *Chesapeake Bay, Sediments, Bottom sediments, Surface water, Benthic environment, Toxicity, Sediment transport, Fish, Oysters, Mollusks.

The major source of Kepone contamination in Virginia was the manufacturing plants at Hopewell. However, the compound is also generated in the production and degradation of Mirex, and many environmental samples outside of this area of Virginia also record the presence of kepone. In the Chesapeake Bay, moving northward from the James River, most marine species exhibit a significant decline in kepone concentrations. Residues in bottom feeders decline very rapidly, reflecting a decrease in contamination of the immobile food supplies. Piscivorous species showed slower rates of decontamination, possible because their primary food sources were mobile and transported kepone residues to greater distances. Bluefish showed less of a decline in contamination than any other finfish, as these are highly mobile and move in and out of the James to other areas of the bay. The bottom sediments of the James have acted to some degree as a reservoir for kepone. From the bottom it cycles to solution and is taken up by plants and animals, to be returned eventually to the sediments on death of the organisms. Benthic animals may take up kepone directly and transfer it to their predators. Evidence from 1979 suggests that surface sediments are demonstrating lessening levels of contamination. It is noted, however, that a major hurricane, which has not hit this area since the 1950s, could stir up the bottom and redistribute the sediments overnight, possibly even moving the contamination into the Chesapeake Bay. INFLUENCE OF GASEOUS NITRIC ACID ON SULFATE PRODUCTION AND ACIDITY IN RAIN,
Environmental Sciences Research Lab., Research Triangle Park, NC.
J. L. Durham, J. H. Overton, and V. P. Aneja.
Atmospheric Environment, Vol 15, No 6, p 1059-1068, 1981. 4 Fig, 5 Tab, 33 Ref.

Descriptors: *Acid rain, *Mathematical models, *Nitric acid, Acidity, Hydrogen ion concentration, Air pollution effects, Sulfates, Simulated rainfall.

A physico-chemical subcloud rain model was used to study the pollutant chemistry leading to rain acidification. In the model, drops fall through a polluted region containing trace gases CO2, O3, SO2, HNO3, NO, and NO2. The concentration of each chemical species within a drop was calculated. Subcloud scavenging of HNO3 may control acidification during the beginning of a rain event and may have more control over the final pH than SO2. In fact, gaseous HNO3 inhibits the production of sulfate in rain by lowering the pH. Acidification was not caused by the oxides of nitrogen, NO and NO2. In-cloud scavenging can have greater control over final acidity than subcloud scavenging. Furthermore, gaseous HNO3 is removed from the atmosphere more rapidly than SO2 or O3. In this simulation, cumulative NO3 decreased by 42% in one hour, while SO4 and pH slightly increased. This theoretical study did not consider the formation of rain in the polluted zone, and the effect of in-cloud processes are ignored. (Small-FRC)

THE ORGANIC POLLUTION OF RIVER CUBILLAS (GRANADA, SOUTH SPAIN),
Granada Univ. (Spain). Dept. of Ecology.
J. C. Canteras.
Acta Hydrobiologica, Vol 22, No 4, p 439-448, 1980. 3 Fig, 1 Tab, 6 Ref.

Descriptors: *Organic matter, *Low flow, *Rivers, Water pollution sources, Industrial waste, River flow, Bacteria, Chemical properties, Cubillas River, *Spain.

The pollution of the River Cubillas is investigated with emphasis on the relationship between the heterotrophic bacterial population and various chemical factors which are affected by the organic matter draining from stored olives at oil mills. The river was sampled at six locations, and the following parameters were determined: oxygen, nitrates and nitrites, total alkalinity, and phosphates. The slide sprinkling technique was used to determine the heterotrophic bacterial population. The

number of correlations between variables increased with the degree of pollution. The oil mill located between the first and second sampling stations did not greatly affect the river. The repeated addition of wastes along the river from several mills is the source of the problem because of the river's low flow with no possibility of self-purification between one mill and the next. PERSISTENCE AND DISTRIBUTION OF ERYSIPELOTHRIX RHUSIOPATHIAE AND BACTERIAL INDICATOR ORGANISMS ON LAND USED FOR DISPOSAL OF PIGGERY EFFLUENT,
Victoria Dept. of Agriculture (Australia). Attwood Veterinary Research Lab.
D. S. Chandler, and J. A. Craven.
Journal of Applied Bacteriology, Vol 48, No 3, p 367-375, June, 1980. 3 Tab, 16 Ref.

Descriptors: *Animal wastes, *Land disposal, *Animal diseases, Waste disposal, Bacteria, Bioindicators, Environmental effects, Agriculture, Victoria, *Australia.

Effluent was sampled from 35 Victorian commercial piggeries and tested for the presence of Erysipelothrix rhusiopathiae, the cause of swine erysipelas. Also, the survival of the organism in soil and pasture used for the disposal of untreated piggery waste was determined. The organism was isolated from 15 of the 40 samples. It was found at disposal sites for up to two weeks after application of effluent. It was more common in soil than pasture. The survival of bacterial indicator organisms was determined and fecal coliforms in top soil survived 8 to 19 days and 5 to 12 days on pasture. Fecal streptococci survived 10 to 14 days in soil and 8 to 11 days on pasture. Laboratory studies indicated that the death rate of Erysipelothrix rhusiopathiae was six times greater than E. coli in soil at field capacity. Animals grazing on effluent disposal sites would be more likely to ingest Ery. rhusiopathiae from fecal material and topsoils of disposal sites than from pasture material. The fast decay rate means the risk of infection would be low by the time a hundred- or thousand fold reduction in E. coli or fecal coliform numbers occurred. (Small-FRC)

ASSESSMENT OF AIRBORNE ORGANIC CONTAMINANTS IN THE GREAT LAKES ECOSYSTEM,
Minnesota Univ., Minneapolis. Dept. of Civil and Mineral Engineering.
J. J. Eisenreich, B. B. Looney, and J. D. Thornton.
In: 1980 Annual Report - A Perspective on the Problem of Hazardous Substances in the Great Lakes Basin Ecosystem. Appendix A, November, 1980. 150 p. 36 Tab, 199 Ref. International Joint Commission, Windsor, Ontario.

Descriptors: *Lakes, *Organic wastes, *Precipitation, *Organic compounds, *Water pollution sources, *Air pollution effects, Organic pesticides, Air pollution, Lake sediments, Acid rain, Chemical precipitation, Chlorinated hydrocarbons, Hydrocarbons, Water-sediment interfaces, *Great Lakes basin, Ecosystems.

No systematic survey of the identity, concentrations and frequency of occurrence of true organics has been performed in the Great Lakes Basin ecosystem; however, a review of literature and past research was conducted for both dry and wet deposition to assess current needs regarding the identification and control of organic airborne contaminants. Atmospheric deposition was found to be greater for Lakes Superior, Michigan, and Huron than for Lakes Erie and Ontario, as a result of general mass air circulation patterns, a large lake/basin area, and higher atmospheric concentrations. While atmospheric deposition of airbone PCBs is the most serious known toxic organic problem affecting Great Lakes water quality, other trace organics for which the atmospheric pathway is important include DDT-group pesticides, alpha-BHC, beta-endosulfan, methoxychlor, PAHs, and phthalate esters. The report recommends that a study be made of land-based sampling vs. over-lake sampling, the sources of airborne trace organics, and the transport of organics from urban areas to the lakes. In addition, the atmospheric pathway for the input of trace organics should be compared to other input pathways including tributary inflow, municipal and industrial discharges, and erosion. ASSESSMENT OF AIRBORNE INORGANIC CONTAMINANTS IN THE GREAT LAKES,
Illinois Inst. of Tech., Chicago. Pritzer Dept. of Environmental Engineering.
H. E. Allen, and M. A. Halley.
In: 1980 Annual Report - A Perspective on the Problem of Hazardous Substances in the Great Lakes Basin Ecosystem, Appendix B, November, 1980. 160 p. 19 Fig, 22 Tab, 63 Ref, 5 Append. International Joint Commission, Windsor, Ontario.

Descriptors: *Lakes, *Water pollution sources, *Precipitation, *Heavy metals, *Air pollution effects, *Chemical precipitation, Trace metals, Air pollution, Acid rain, Water-sediment interfaces, Lake sediments, Data interpretation, On-site data collections, *Great Lakes.

Many studies of the atmospheric deposition of inorganic contaminants in the Great Lakes area have been conducted to determine the ecological and geochemical significance of such constituents as nitrate, phosphates, aluminum, cadmium, chromium, copper, iron, manganese, lead, and nickel. This report reviews these studies and concludes that true loading to the Great Lakes may never be fully known. Efforts to increase knowledge of atmospheric deposition should include consideration of sampling sites that (1) represent a relatively large area; (2) consider the optimum above-ground or ground-level height for collectors; (3) include an adequate snow collection method; (4) include rural and urban sites for any loading estimate of local point sources; (5) use wet and dry samplers; and (6) involve coordination between Canadian and U.S. monitoring efforts. It is important that data studies consider the impact and measurement of contaminated samples and the risk of sample evaporation. The report recommends that a joint monitoring network be established between the U.S. Environmental Protection Agency and the Canada Centre for Inland Waters. (Garrison-Omniplan)

Descriptors: *Chemical precipitation, *Air pollution effects, *Air pollution, *Chemical degradation, *Precipitation, Acid rain, Organic compounds, Catalysts, Electro-phoresis, Incineration, Waste disposal, Oxidation.

Total organic air emissions in 1978 for North America were estimated at 33 million tons, of which 38% derived from power sources used in the transportation industry and 27% were from organic solvents, such as paints, and dry cleaning and degreasing processes. This report reviews the complex issue of organic pollution sources and the available technologies for the degradation of organic pollutants. The conclusion is drawn that in most instances, current technology is capable of reducing discharges to tolerable levels. Each approach to reducing emissions---recycling, reducing quantities emitted, and reducing effects of emissions---presents technical problems. Specific reduction methods include electrostatic precipitation, chemical processes, control of ducted particulate or droplet material, control of ducted vapors, control of fugitive emissions, condensation, and incineration. The development of poison-resistant catalysts, and ceramic supports for the catalysts, has improved the capability of catalytic oxidation at temperatures well below those required for thermal oxidation of organics. It is in the use of the so-called phoretic effects---electrophoresis, diffusiophoretics, and thermophoresis---that the development of scrubber technologies has progressed most. (Garrison-Omniplan)

HYDROGEOCHEMISTRY AND SIMULATED SOLUTE TRANSPORT, PICEANCE BASIN, NORTHWESTERN COLORADO,
Geological Survey, Lakewood, CO. Water Resources Div.
S. G. Robson, and G. J. Saulnier Jr.
Available from Supt. of Documents, GPO, Washington, DC 20402, Price, $4.25. Geological Survey Professional Paper 1196, 1981. 65 p, 45 Fig, 4 Tab, 64 Ref.

Descriptors: *Geochemistry, *Groundwater, *Oil shale, *Mine drainage, Model studies, Aquifer characteristics, Water quality, Water pollution sources, Surface-groundwater relations, *Colorado, Piceance basin, Solute-transport modeling.

Oil-shale mining activities in Piceance basin in northwestern Colorado could adversely affect the ground- and surface-water quality in the basin. This study of the hydrology and geochemistry of the area used ground-water solute-transport-modeling techniques to investigate the possible impact of the mines on water quality. Maps of the extent and structure of the aquifer were prepared and show that a saturated thickness of 2,000 feet occurs in the northeast part of the basin. Ground-water recharge in the upland areas in the east, south, and west parts of the basin moves down into deeper zones in the aquifer and laterally to the discharge areas along Piceance and Yellow Creeks. The saline zone and the unsaturated zone provide the majority of the dissolved solids found in the ground water. Precipitation, ion-exchange, and oxidation-reduction reactions are also occuring in the aquifer. Model simulations of ground-water pumpage in tracts C-a and C-b indicate that the altered direction of ground-water movement near the pumped mines will cause an improvement in ground-water quality near the mines and a degradation of water quality downgradient from the tracts. Model simulations of mine leaching in tract C-a and C-b indicate that equal rates of mine leaching in the tracts will produce much different effects on the water quality in the basin. Tract C-a, by virtue of its remote location from perennial streams, will primarily degrade the ground-water quality over a large area to the northeast of the tract. Tract C-b, by contrast, will primarily degrade the surface-water quality in Piceance Creek, with only localized effects on the ground-water quality. (USGS)

METAL LEACHING FROM SEWAGE SLUDGE ASH,
Connecticut Univ., Storrs. Dept. of Chemical Engineering.
H. E. Klei, D. Sundstrom, and C. Sweeney.
BioCycle, Vol. 22, No 3, p 41-43, May/June, 1981. 4 Fig, 3 Tab, 6 Ref.

Descriptors: *Metals, *Leaching, *Sludge ash, Acid rain, Heavy metals, Ash, Water pollution sources, Fate of pollutants, Incineration, Copper, Chromium, Cobalt, Calcium, Iron, Magnesium, Manganese, Lead, Nickel, Potassium, Sodium, Sludge disposal.

Column elution and batch leaching tests, conducted on unquenched incinerator ash from a wastewater plant, recovered varying amounts of metals using water of pH 5.3 and 4.0. No cobalt, iron, or lead was recovered in the leachates. Water at pH 4.0, simulating acid rain, eluted 27% of the Cu, 79% of Cr, 40% Ca, 28% Mg, 25% Mn, 11% Ni, 20% K, and 21 % Na after a single batch extraction. From 0 to 3.76% metals were leached during column elution tests using 6 bed volumes of liquid. Water of pH 5.3 recovered half to 75% of these amounts. If ash is extracted with water before sending it to the landfill, an appreciable fraction of the Ca and Cr may be recovered. (Cassar-FRC)

TRANSFORMATIONS OF NITROGEN IN A POLLUTED ESTUARY: NONLINEARITIES IN THE DEMAND FOR OXYGEN AT LOW FLOW,
Harvard Univ., Cambridge, MA. Center for Earth and Planetary Physics.
S. C. Wofsy, M. B. McElroy, and J. W. Elkins.
Science, Vol 213, No 4509, p 754-757, August 14, 1981. 2 Fig, 16 Ref.

Descriptors: *Ammonium, *Oxygen demand, *Nitrification, *Low Flow, Fate of pollutants, Sewage bacteria, Oxidation, *Potomac River, Delaware River, *Estuaries, Nitrogen cycle, Model studies, Bacteria, Nitrites, Chemical reactions.

A simple kinetic model was developed to describe the oxidation of sewage ammonium in the Potomac River. Growth of nitrifying bacteria is limited by the supply of ammonium ion, supplied at a constant rate of 200 g N per sec. The oxidation rate varies inversely with fresh water inflow, and the oxygen demand varies as the inverse square of the fresh water inflow rate. The model accounts for observed concentrations of ammonium and nitrous oxide except at stream flows less than 80 cu meters per sec (usual range 20-250 cu meters per sec, mean 130 cu meters per sec). At low flow, peculiar behavior of maximum ammonium concentrations is seen. Peak concentrations increase as flow declines from 200 to 100 cu meters per sec, but decrease below 100 cu meters per sec. Both model and observations agree that between 70 and 100% of the ammonia in the Potomac is removed by oxidation of ammonia to nitrous oxide. The rate of nitrification is lowered by a factor of 1.6 for a reduction in water temperature of 10 degrees C, in agreement with results for bacteria cultures, which gave factors of 1.5-2.2. The model is also applicable to the Delaware River. (Cassar-FRC)

Descriptors: *Bioindicators, *Pathogens, Soil disposal fields, Land disposal, Animal wastes, *Soil properties, Wastewater disposal, Organic wastes, Farm wastes, Viruses, Runoff, Water quality, Soil contamination, Mathematical models, Mathematical equations.

The survival rate of microbial pathogens in the soil after application of wastes is one of the most important factors in determining the number of organisms available for rainfall-runoff transport. A simple conceptual model based on the current state of the art was developed to describe pathogen and indicator organism behavior in land areas receiving animal wastes. The model was used to examine the effects of die-off rate and retention by soil particles on runoff water quality. Microbial die-off was described, assuming first-order kinetics. First order die-off rate constants were calculated from the literature for various pathogens and indicator organisms in soil-water systems. Correction factors were presented to adjust rate constants for changes in temperature, moisture, and pH of the soil. A 10 degree C rise in temperature was found to double the die-off rates of the organisms studied. Die-off rates also increased with a decrease in soil moisture. Soils with pH between 6 and 7 had slow die-off rates. A linear isotherm was assumed in describing the retention of pathogens and indicator organisms by soil particles. Increases in soil surface area and clay content of the soil resulted in increases in the retention of viruses. Leaching and surface runoff transport processes were considered both for land areas receiving direct applications of animal wastes and for pastures and rangeland watershed. Several areas requiring further research with respect to pathogen behavior in soils treated with organic wastes were identified. (Carroll-FRC)

METHYLATION OF TRIMETHYLTIN COMPOUNDS BY ESTUARINE SEDIMENTS,
California Univ., Berkeley. Naval Biosciences Lab.
H. E. Guard, A. B. Cobet, and W. M. Coleman, III.
Science, Vol 213, No 4509, p 770-771, August 14, 1981. 1 Fig, 12 Ref.

Descriptors: *Tin compounds, *Methylation, *Sediments, Fate of pollutants, Chemical reactions, *Estuarine environment, Biotransformation, Organotin compounds, Biocides, *Fouling.

The potential for environmental methylation of trialkyl tin compounds was studied in the laboratory using trimethyltin hydroxide as a model compound and anoxic, organic-rich estuarine tidal flat sediments. After 80 days' incubation, the biologically active sediments produced 2.7 times the amount of volatile tetramethyltin (maximum 2.4% of the added trimethyltin hydroxide) as compared with autoclaved control sediments. No methyltin compounds were produced in the absence of added trimethyltin hydroxide or in the presence of trimethyltin hydroxide in seawater or seawater-bentonite. The amount of trimethyltin produced was doubled by additions of 15 g Na2S and increased 70% by addition of 0.30 g sodium acetate. Adding these compounds to autoclaved sediments did not affect the amount of trimethyltin produced. These studies demonstrate a possible abiotic pathway for the formation of trimethyltin by a Lewis-base redistribution of trimethyltin hydroxide. Methylation of tin is probably of minor importance in the environment. It occurs in low yield, and the volatile, water-insoluble product should escape to the atmosphere, not accumulate in the marine environment. It is likely that the tributyltin compounds used widely as antifouling agents would also methylate to a minor degree. (Cassar-FRC)

URANIUM CONCENTRATION IN THE GROUND WATERS OF THE PULLMAN-MOSCOW BASIN, WHITMAN COUNTY, WASHINGTON, AND LATAH COUNTY, IDAHO,
Washington State Univ., Pullman. R. L. Albrook Hydraulic Lab.
V. T. Ichimura, and J. W. Crosby, III.
Northwest Science, Vol 55, No 1, p 10-22, February, 1981. 6 Fig, 1 Tab, 13 Ref.

Descriptors: *Uranium, *Groundwater pollution, *Groundwater basins, Washington, Idaho, *Pullman-Moscow Basin, Nuclear track technique, Leaching, Water pollutants, Path of pollutants.

The Pullman-Moscow basin is located in the southeastern part of Whitman County, Washington, and west-central Latah County, Idaho. A recent increase of uranium exploration and an earlier finding of anomalously high radiation background in samples of basin groundwater prompted this study of the concentration of dissolved uranium in the Pullman-Moscow basin. A high-sensitivity nuclear track technique, capable of detecting concentrations as low as 5 parts per trillion, was used in this study. The sampling procedure included on-site measurements of temperature, pH, and conductivity. Analysis of the samples using the nuclear track technique showed uranium concentrations as high as 25 parts per billion. Any uranium concentration higher than 6.2 parts per billion was considered anomalous. About 6.8% of the samples fell into this category. Clusters of high uranium concentration were located in groundwaters from the east and southeast sections of the Pullman-Moscow basin on or near the basalt-granite rock contact. These higher concentrations of uranium are probably the result of local leaching of uranium from granitic rocks by oxidizing meteoric waters recharging the basin. Deep, high-yield municipal and domestic wells in the central and western parts of the basin were found to contain very low uranium concentrations, probably as a result of the reducing conditions in the deep groundwater environment of the basin. Although attempts to correlate conductivity, pH, and well depth with uranium concentrations demonstrated the absence of any correlation, samples that had high uranium concentrations generally also had high conductivities. Descriptors: *Macrophytes, *Bioindicators, *Radioactivity, *Radioactive wastes, Aquatic plants, Hydrogen ion concentration, Cesium, Cobalt, Plutonium, Water pollution sources, Retention.

Relative uptake and accumulation of Co60, P32, and Cs134 by three aquatic macrophytes were determined in the Ismailia Canal, which is adjacent to the Egyptian Nuclear Research Center. The plants were Lemna gibba, a floating plant; Ceratophyllum demersum, a submerged plant near the water's surface; and Potamogeton crispus, a rooted submerged plant. Uptake of radionuclides decreased at increasing pH from 5 to 9. When pH was constant, uptake increased with increased contact time. Concentration factors obtained for Co60 were higher than those for P32, while Cs134 showed the lowest concentration factors for all three macrophytes. Maximum uptake values were found at all pH values after a contact time from 4 to 12 days. Thus, the tested macrophytes proved to be reliable biological indicators. They may be used in studies to develop safe limits for disposal of low level radioactive wastes and to evaluate the hazards of the accidental release of radioactivity to the canal water. (Small-FRC)

Descriptors: *Organic compounds, *Contamination, *Wastewater, *Environmental effects, *Indusrial waste, Chemical wastes, Chlorine, Water pollution, Lagoons, Waste treatment, Discharge frequency, Flow discharge, Fish physiology, Toxicity, Carcinogens, Fish populations, Water sampling, Streams, Adrian, *Michigan.

Results which trace waterborne methylene bis (2-chloroaniline) (M2CA) and 2-chloroaniline (2CA) contamination from an industrial waste treatment lagoon in Michigan through the municipal wastewater treatment plant and surface runoff to a stream are reported. Sludge, sediment, fish, and water samples were collected and analyzed. Samples were extracted successively with ethyl acetate and methanol, and analyzed on gas chromatographic columns. M2CA was the dominant compound in the waste lagoon sediment, while 2CA is the dominant compound at the sewage treatment plant sludge. The 2CA may be more readily mobilized through the wastewater systems because of its water solubility or lesser tendency to sorb to sediments. Contamination was found in a deep well on the manufacturing site and in surface runoff from the site. No M2CA was detected in water from the Raisin River near the sewage treatment plant outfall. Possible traces of M2CA were found in the influent and effluent water from the municipal sewage treatment plant. Results of the fish tissue analysis suggest that the contaminant residues are chemically bound to macromolecules of the tissue. (Titus-FRC)

Descriptors: *Absorption, *Uptake, *Benthos, *Pesticides, Forestry, Accumulaton, Benthic fauna, Benthic flora, Plankton, Aquatic life, *Lakes, Organic compounds, Water pollution, Zooplankton, Environmental effects, Water sampling, Fenitrothion, Fate of pollutants, *Peabody Lake, New Brunswick, Canada.

Results of a preliminary survey on the response of plankton and benthic algae of Peabody Lake in New Brunswick, Canada to fenitrothion spray formulations are presented. Fenitrothion is an organophosphate insecticide used selectively for forest protection against the spruce budworm. The survey indicates that concentrations of fenitrothion diminish rapidly under conditions where water temperatures and pH values ranged from 11 to 15 degrees Centigrade and 6.1 and 7.2 respectively. Fenitrothion is actively taken up by plankton to a degree that depends on various environmental conditions including growth rates, seasonal variation, and bloom formation. The algal species observed in the Peabody lake did not suggest any toxicity or polluted conditions. (Titus-FRC)

MERCURY AND SELENIUM CONCENTRATIONS IN FISH, SEDIMENTS, AND WATER OF TWO NORTHWESTERN QUEBEC LAKES,
Noranda Research Centre, Pointe Claire (Quebec). Process Technology Dept.
M. R. Speyer.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 3, p 427-432, 1980. 3 Tab, 15 Ref.

Descriptors: *Fish populations, *Sediments, Water pollution, *Lakes, Heavy metals, Toxicity, Fish physiology, *Mercury, *Selenium, Environmental effects, *Fish toxins, Ecosystems, Trace metals, Aquatic environment, Aquatic organisms, Chemical analysis, *Quebec.

Findngs of a detailed study conducted in Quebec are presented. The study concerned mercury in the aquatic ecosystem and techniques to reduce the toxicity of mercury accumulated by aquatic organisms. The interaction between mercury and selenium in biological systems is both antagonistic and synergistic. Fish samples from two lakes were obtained and analyzed for mercury and selenium. Results showed significant differences between the mercury and selenium concentrations of fish samples from the two lakes. Elevated selenium concentrations in fish from Lake Dufault corresponded to elevated background selenium concentrations. The two lakes have similar physical dimensions and mining histories, but have different types of bottoms. Lake Dufault has a heavy-metal enriched sludge sediment covered by glacial clay, while Lake Duparquet has a fine silt overlying glacial clay. (Titus-FRC)

ENRICHMENT OF THE AGRICULTURAL HERBICIDE ATRAZINE IN THE MICROSURFACE WATER OF AN ESTUARY,
Smithsonian Institution, Edgewater, MD. Chesapeake Bay Center for Environmental Studies.
T. L. Wu, L. Lambert, D. Hastings, and D. Banning.
Bulletin of Environmental Contamination and Toxicology, Vol 24, No 3, p 411-414, 1980. 1 Fig, 1 Tab, 10 Ref.

Descriptors: *Agricultural chemicals, *Agricultural runoff, Crop production, *Estuaries, *Plankton, Agricultural watersheds, Agriculture, Farm wastes, Water pollution, Organic compounds, Diffusion, Convection, Pollutants, Water sampling, Pellicular water, Seasonal variation, *Herbicides, *Atrazine.

Results of a study of the distribution and concentration of atrazine in the Rhode River estuary in Maryland are presented. Atrazine is an herbicide commonly used to control broadleaf weeds and grasses in cornfields. During two seven-month sampling periods the peak concentractions were detected in August. Concentrations in microsurface and bulk water decreased in October. The effects of a high concentration of herbicides in the microsurface layer on the diversity and species composition of bacteria, phytoplankton, submerged macrophytes, and zooplankton exposed to the surface microlayer are not known. THE IMPACT OF AN INDUSTRIALLY CONTAMINATED LAKE ON HEAVY METAL LEVELS IN IT'S EFFLUENT STREAM,
Purdue Univ., Lafayette, IN. Dept. of Bionucleonics.
T. G. Adams, G. J. Atchison, and R. J. Vetter.
Hydrobiologia, Vol. 69, No 1/2, p 187-193, March, 1980. 1 Fig, 6 Tab, 27 Ref.

Descriptors: *Cadmium, *Zinc, *Stream degradation, Lakes, Stream pollution, Ecology, *Industrial wastes, Atomic absorption spectroscopy, Heavy metals, Water quality, Water pollution. Palestine Lake, Indiana, *Electroplating, Wastewater.

Levels of cadmium and zinc were determined in a stream receiving water from an industrially contaminated lake. Water samples were collected in Williamson Ditch (a contaminated stream flowing into Palestine Lake), Trimble Creek (a stream draining Palestine Lake), and the Tippecanoe River (a river receiving Trimble Creek). Atomic absorption spectrophotometry was used to analyze water, sediment, plant, fish, and clam samples. In Trimble Creek unweighted mean metal concentrations were: water, 51 microgram Zn/liter, 4.2 microgram Cd/liter; sediment, 592 microgram Zn/g, 48.4 microgram Cd/g; plants, 375 microgram Zn/g and 7.91 microgram Cd/g; fish, 145 microgram Zn/g and 6.02 microgram Cd/g. In general, concentrations were higher in Williamson Ditch and lower in the Tippecanoe River. The water is polluted by wastes from an electroplating plant. Results indicate that a large percentage of the metal wastes are not held in the lake. The stream which is the outlet for the lake contains metals in concentrations higher than background levels reported for other aquatic systems. (Small-FRC)

DEGRADATION OF HYDROCARBONS IN OXIDIZED AND REDUCED SEDIMENTS,
Louisiana State Univ., Baton Rouge, Lab. for Wetland Soils and Sediments.
R. D. Delaune, G. A. Hambrick, III, and W. H. Patrick, Jr.
Marine Pollution Bulletin, Vol 11, No 4, p 103-106, April, 1980. 5 Fig, 10 Ref.

Descriptors: *Degradation, *Hydrocarbons, *Sediments, Wetlands, Gulf of Mexico, Oxidation, *Salt marshes, *Louisiana, Oxidation-reduction potential, Anaerobic conditions, Aerobic conditions.

The effect of sediment oxidation-reduction or redox potential on hydrocarbon degradation was investigated in samples collected from a Gulf Coast salt marsh. Carbon-14 labelled octadecane, an alkane hydrocarbon, and carbon-14 labelled naphthalene, an aromatic hydrocarbon, were used in this study. Both of these hydrocarbons were very stable in the anaerobic sediment. Naphthalene did not degrade at all in the anaerobic sediment. Naphthalene showed less degradation in both oxidized and reduced sediment than did octadecane. Hydrocarbon degradation was significantly increased by a shift from strict anaerobic conditions in the sediment, where the hydrocarbons are stable and only a few microbial species function, to aerobic sediment conditions where aerobic and facultative anaerobic bacteria function. The redox profile of the sediment cores showed a distinct oxidized surface layer, between 5 and 10 millimeters thick, in which hydrocarbons were oxidized. Beneath this layer, anaerobic conditions, in which hydrocarbons did not degrade, prevailed. The study results clearly demonstrate that petroleum hydrocarbons in estuarine environments are significantly affected by the oxidation-reduction status of the sediment in contact with the hydrocarbons, and that aromatic hydrocarbons which enter an anaerobic sediment environment may persist. TRANSPORT OF SALTS IN SOILS AND SUBSOILS,
Volcani Inst. of Agricultural Research, Bet Dagan (Israel). Div. of Soil Physics.
E. Bresler.
Agricultural Water Management, Vol 4, No 1-3, p 35-62, 1981. 14 Fig, 23 Ref.

Descriptors: *Salts, *Soil water, *Estimating equations, Flow, Mathematical studies, Infiltration, Evaporation, Arid lands, Salinity, Water quality, *Israel, Agriculture, *Solute transport.

Factors affecting the movement of salts in saturated and unsaturated soils and subsoils under dryland conditions are reviewed. The transport occurring in homogeneous soils is described, and the factors affecting salt transport are quantitatively formulated. Equations are presented which describe combined diffusion-convection transient transport and

miscible displacement of salts and non-steady water flow. Equations and boundary conditions are described for infiltration, redistribution, and evaporation, in terms suitable for mathematical modeling. One-dimensional vertical profiles of non-interactive salts are described for homogeneous, bare fallow soil. Where physico-chemical interaction takes place between solution and soil matrix, these effects are considered. Also, vegetation effects are considered. Salt dispersion and distribution in heterogeneous fields are also discussed, including the concentration distributions for steady and transient leaking. A knowledge of these processes makes possible the development of optimum management practices to prevent the salinization of groundwaters, streamflows, and farmland. (Small-FRC)

EVALUATION OF WINTER APPLICATION OF LIQUID SLUDGE TO FARMLAND,
Guelph Univ. (Ontario). Dept. of Land Resource Science.
T. Bates, J. W. Ketcheson, R. A. Johnston, and Y. K. Soon.
Water/Engineering and Management, Vol REF, No HB, p R155-156, 1981. 2 Tab.

Descriptors: *Sludge, *Land disposal, Runoff, Seasonal variation, Nitrogen, Phosphorus, Farms, Rainfall, Snowmelt, Thaw, Heavy metals, Water pollution sources, Path of pollutants, Ontario.

Field runoff was investigated from fall, winter, and spring applied sludge over a five year period on a silt loam soil at a location north of Guelph, Ontario. Rainfall averaged 858 mm and snowfall averaged 1,618 mm. Fluid anaerobically digested sludge from the North Toronto treatment plant was used for the study. Sewage was treated with ferric chloride for phosphorus removal and received secondary treatment with activation. Sludge was applied at 200 and 800 kg nitrogen/hectare rates on areas with 2% and 6% slopes. Treatments were replicated twice on each slope. Water was collected after each runoff event and total runoff, solids, and total and soluble nitrogen, phosphorus and metals were measured. Total runoff in winter was four times as much as in summer, with very little difference between the 2% and the 6% slopes. In summer there was more runoff from the steeper slope. Annual losses of N and P ranged from less than 1% to 10% of that applied and were greater in summer except for January, when total N losses were greater in the winter. Nearly all the nitrogen and phosphorus in winter runoff was water soluble, but in summer runoff only 1-2% was water soluble. Losses of nitrogen and phosphorus were high from November and January applied sludge when rainfall or snow melt immediately followed sludge application. The North Toronto sludge was low in metals, but some metal losses did occur, with the effects of slope and time of application similar to those for nitrogen and phosphorus. It was noted that fluid sludge should not exceed 1.5 cm depth on the soil surface nor supply more than the crop requirements for available nitrogen. Fluid sludge should not be applied near waterways. (Baker-FRC)

THE FATE OF HEAVY METALS IN THE RUHR SYSTEM AND THEIR INFLUENCE ON DRINKING WATER QUALITY,
Ruhrverband, Essen (Germany, F. R.).
K. R. Imhoff, and P. Koppe.
Water Science and Technology, Vol 13, No 3, p 211-225, 1981. 4 Fig, 9 Tab, 18 Ref.

Descriptors: *Heavy metals, *Nickel, *Drinking water, Path of pollutants, *Ruhr River, Sediments, Water pollution control, *Industrial wastewater, Artificial recharge, Recharge, Infiltration, Chelation, Water treatment, Wastewater treatment, Adsorption, Pretreatment of water, Sludge disposal, Water quality control, Manganese, Zinc, Lead, Chromium.

Nickel is used to illustrate the path of heavy metals from the factory to the drinking water supply of the heavily populated and industrialized Ruhr River basin. Ni concentrations (in mg per liter) in various influents and effluents are as follows; untreated wastewater from the 300 electroplating plants in the basin, up to 1,000; pretreated effluent, 10; combined industrial and municipal wastewater influent, 0.5; municipal treatment plant effluent, 0.3; river water (flow 40 cu meters per sec) downstream of the effluent discharge, 0.05; and waterworks reservoir, 0.04. Drinking water obtained from artificial groundwater recharge contains 7.9 micrograms per liter of Ni, and from bank infiltration, 4.5 micrograms per liter (original river water, about 38.5 micrograms per liter). Most heavy metals decreased similarly in the path from water supply source to tap, with the exception of Mn in bank filtration and Cu in artificial groundwater recharge. In the distribution system concentrations of Zn decreased; Pb, Cr, and Cd did not change; and Cu and Ni increased to 62 and 13 micrograms per liter, respectively. Measures are suggested to further reduce heavy metals in drinking water: supervision in industries and avoidance of complexing agents in industry and detergents. Other problems are the high levels of metals in land applied sewage sludge and possible mobilization of metals from river sediments and subsoil. (Cassar-FRC)

BIOCONCENTRATION OF PESTICIDES BY EGG MASSES OF THE CADDISFLY, TRIAENODES TARDUS MILNE,
Illinois Natural History Survey, Urbana.
D. Belluck, and A. Felsot.
Bulletin of Environmental Contamination and Toxicology, Vol 26, No 3, p 299-306, March, 1981. 3 Fig, 1 Tab, 18 Ref.

Descriptors: *Eggs, *Caddisflies, *Bioaccumulation, *Pesticides, Aquatic insects, Biological magnification, Solubility, Fate of pollutants, Organic compounds.

Significant quantities of pesticides were accumulated by caddisfly egg masses (Triaenodes tardus Milne) from water with the following concentrations of pesticides: DDD, DDT, and HCB, 1 ppb; carbofuran, 8 ppb; dieldrin, 20 ppb; and methoxychlor, terbufos, malathion, diflubenzuron, and monuron, 100 ppb. The maximum bioconcentration factors, which correlated with phsyicochemical properties of the pesticides, were as follows: DDD, 2580; HCB, 550; DDT, 250; dieldrin, 100; methoxychlor, 80; diflubenzuron, 20; terbufos, 10; and carbofuran, malathion and monuron, zero. DDD, HCB, and DDT bioconcentration factors reached a peak at 72-96 hours, then declined sharply. Dieldrin and methoxychlor curves were not declining by the end of the 120 hour test. The remainder of the pesticides showed a small rise at 72-96 hours and decreased slightly. A strong correlation existed between water solubility of the pesticides and 72 hour bioconcentration factors. (Cassar-FRC)

ROLE OF SOLUTE-TRANSPORT MODELS IN THE ANALYSIS OF GROUNDWATER SALINITY PROBLEMS IN AGRICULTURAL AREAS,
Geological Survey, Reston, VA.
L. F. Konikow.
Agricultural Water Management, Vol 4, No 1/3, p 187-205, 1981. 11 Fig, 1 Tab, 20 Ref.

Descriptors: *Salinity, *Groundwater, Farming, Groundwater movement, Soil properties, Model studies, Solute transport, Salts, Surface-groundwater relationships, Hydrology, *Agricultural watersheds.

Accurate technical evaluations of the sources of salinity and of salt transport in a variety of hydrogeologic settings are important if control of groundwater salinity in agricultural areas is to be achieved. Two examples are given which illustrate the crucial role of groundwater in transporting and dispersing salts through a local or regional aquifer to the land surface or into a surface water body and the value of a model as an investigative tool to understand the processes and parameters controlling the movement and fate of the salt. The purpose of a model that simulates solute transport in groundwater is to compute the concentration of a dissolved chemical species in an aquifer at any specified place and time. The increase in salinity of groundwater and surface water in the Arkansas River Valley of south-eastern Colorado is primarily related to irrigation practices. An 18 km reach of the valley was selected for a detailed study. A detailed study was also performed in a nonirrigated area of a wheat field on a dryland farm in the South Platte River valley, near Denver. The model was also used to test some possible water management alternatives, including the coupling of artificial recharge with construction and operation of hydraulic sinks along the northern boundary of the Rocky Mountain Arsenal, which is adjacent to the dryland farm area. Such complex engineering solutions may be feasible in cases where the salt problem is predominantly related to an isolated and specific industrial activity, as is the case here. However, use of such measures in areas where salt seeps out due to agricultural activities is not likely to be helpful. (Baker-FRC)

HEAVY METAL CONTENTS IN SOME MACROPHYTES FROM SAGINAW BAY (LAKE HURON, U.S.A.),
Cranbrook Inst. of Science, Bloomfield Hills, MI.
J. R. Wells, P. B. Kaufman, and J. D. Jones.
Aquatic Botany, Vol 9, No 2, p 185-193, September, 1980. 1 Tab, 11 Ref.

Descriptors: *Heavy metals, *Macrophytes, *Lakes, Water pollution control, Algae, Bioaccumulation, Water pollution effects, Lake Huron, *Saginaw Bay.

An investigation was designed to see which aquatic species, if any, offered potential for the removal of heavy metals from freshwater lakes. During the summer of 1977 in Saginaw Bay (Lake Huron), 71 plants representing 22 species were collected and analyzed for heavy metal content. Neutron activation analysis was used to measure levels of Ag, As, Ba, Cd, Ce, Co, Cr, Cs, Ni, Rb, Sb, Se, Th, U, and Zn in the 21 spermatophytes and one green alga. Both submersed and emergent species showed considerable accumulations of a range of metals. Different organs of the same species or of the same plant were found to vary widely in concentrations of the same element. Highest element uptake amounts were found near the mouth of the Saginaw River. Some plants growing in the polluted bay contained lower amounts of certain metals than did plants of the same species growing in a wilderness area. Thus, plants can accumulate large amounts of metals, but these high concentrations may not result from water pollution. (Small-FRC)

SALINE SEEP DEVELOPMENT AND CONTROL IN THE NORTH AMERICAN GREAT PLAINS - HYDROGEOLOGICAL ASPECTS,
Montana Bureau of Mines and Geology, Butte.
M. R. Miller, P. L. Brown, J. J. Donovan, R. N. Bergatino, and J. L. Sonderegger.
Agricultural Water Management, Vol 4, No 1/3, p 115-141, 1981. 14 Fig, 2 Tab, 30 Ref.

Descriptors: *Seepage, *Salinity, Chemical properties, *Groundwater, Contamination, Water pollution sources, Groundwater movement, Seepage control, Hydrology, Geohydrology, Groundwater hydrology, Farming, Path of pollutants, *Great Plains.

Hydrogeological aspects of saline seeps are discussed, emphasizing the formation and development, regional extent and potential impacts, and effective control practices for such seeps. Dryland salinity is caused by a combination of cultural, climatic, and hydrogeological conditions. The process begins with excess water percolating down beneath the root zone, picking up soluble salts, accumulating on shallow, less-permeable layers, and forming a local groundwater flow system which moves saline water from the recharge to the discharge area or seep, where it evaporates, depositing the salts on the surface. Geological conditions favorable for such development exist throughout the Northern Great Plains region. There, sufficient soluble salts are available in the upper 6 meters of the soil profile to continue existing saline seeps for the next 25-100 years. Shallow groundwater resources appear to be showing signs of contamination by the saline seep process. High concentrations of dissolved solids, nitrates, and selenium are the most troublesome. Alternate crop-fallow farming techniques allow significant quantities of water to move beneath the root zone, activating the local groundwater flow system and contributing to dryland salinity. The use of deep-rooted perennial crops, flexible cropping systems, and surface drainage of cultivated upland recharge areas will help control dryland salinity. Research results are presented from ten years of study on a typical site, the Hanford-Bramlette test area, about 56 km northeast of Great Falls, Montana, with an area of about 65 ha. (Baker-FRC)

IMPACT OF WATER RESOURCE DEVELOPMENT ON SALINIZATION OF SEMI-ARID LANDS,
California Univ., Davis. School of Civil Engineering.
G. T. Orlob, and A. Ghorbanzadeh.
Agricultural Water Management, Vol 4, No 1/3, p 275-293, 1981. 9 Fig, 14 Ref.

Descriptors: *Salt balance, *River basin, *California, *San Joaquin River, Drainage, Catchment areas, Model studies, Rivers, Farming, *Tile drainage, Semiarid lands.

The development of water resources in the San Joaquin Valley of California is reviewed. The valley is one of the most productive agricultural areas of the world. All of its major rivers have been regulated for power production, water supply, flood control and irrigation. Through the Central Valley Project water was impounded and subsequently diverted to the Tulare Basin to the south. This water was replaced in part by importation from the Sacramento-San Joaquin Delta through the Delta Mendota Canal. This deprived the main river system downstream of Mendota of normal runoff and has led to a serious impact on agriculture in the northern portion of the valley. Changes in water quality have been noted, particularly a reduction in diluting flows of natural runoff and increases in salt accretions to the natural drainage courses due to irrigation drainage. By analyzing runoff and water quality at a sufficient number of locations along the San Joaquin River it was determined that virtually all of the sulfate that reaches Vernalis originates with drainage upstream of the mouth of the Merced River. The salt load carried by the San Joaquin River is steadily increasing. An important step in rectifying the basin's salt balance will be the installation of drainage facilities to convey out of the basin accretions from discrete sources. This will include tile drainage. Model studies have been made, based on the Galerkin-type Finite Element Method. A brief description of one case study using this model is presented. (Baker-FRC)

LEACH CHARACTERISTICS OF COAL-GASIFICATION CHAR,
Carnegie-Mellon Univ., Pittsburgh, PA. Dept. of Civil Engineering.
R. Luthy, P. Vassiliou, and M. J. Carter.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE1, p 81-103, February, 1980. 9 Fig, 6 Tab, 20 Ref.

Descriptors: *Leaching, *Coal gasification, Gasification, *Char, Infiltration, Percolation, Leachates, Carbon, Boron, Molybdenum, Metals, Acidity, Groundwater pollution, Irrigation water, Industrial wastes, Path of pollutants.

Attempts were made to quantify the extent and rate of release of trace elements from char when leached with eluants of varying qualities. Char is produced when carbon conversion is incomplete. The solid waste evaluated here was Hygas western coal char formed at about 63% carbon conversion. In a continuous-flow leaching experiment, 200 g of char was placed loosely in the leaching columns without compaction. Leachate and digested char samples were analyzed for 22 elements using simultaneous multielement analysis by inductively coupled argon-plasma atomic emission spectroscopy. Six different leaching solutions were used: distilled water (simulating rainwater), model intermediate hard water (simulating a typical surface water), model hard water, model acid mine water, acetate-tartrate/hydrosulfite eluant, and deaerated (boiled) tap water (simulating a mildly acidic mineral water with low buffering capacity). The amount of material extracted depended on the nature and strength of the extractant, with pH and buffer capacity of the extractant being important factors. Boron poses a leaching problem due to its deleterious effects on irrigation waters. Molybdenum was the only heavy metal specie routinely identified in the leachate, excluding the acetate-tartrate experiment. This could be a problem, as ground waters carry levels of this element that can give rise to plant concentrations toxic to cattle. (Baker-FRC)

UPTAKE OF POLYCHLORINATED BIPHENYLS BY NATURAL PHYTOPLANKTON ASSEMBLAGES: FIELD AND LABORATORY DETERMINATION OF C14-PCB PARTICLE-WATER INDEX OF SORPTION,
Texas A and M Univ., College Station. Dept. of Oceanography.
D. C. Biggs, C. D. Powers, R. G. Rowland, H. B. O'Connors, Jr., and C. F. Wurster.
Environmental Pollution, (Series A) Vol 22, No 2, p 101-110, June, 1980. 3 Fig, 2 Tab, 19 Ref.

Descriptors: *Polychlorinated biphenyls, *Phytoplankton, *Sorption, Algae, Accumulation, *Fate of pollutants, Chlorinated hydrocarbons, Pesticides, Estuarine environment, Long Island Sound.

Uptake of C14-polychlorinated biphenyls (PCB, 54% chlorine) by a natural phytoplankton community and particulate matter was studied in glass containers in the laboratory and in dialysis cultures in Long Island Sound. Particles at a concentration of 25 million cu micrometers per ml took up 19-22% of the PCB, leaving 1-3% on the glass walls of the container and 70-72% in the water. At particle concentrations 4-fold higher, particles adsorbed 66-69% of the PCB, leaving 22-23% in the water. The percentage sorption appeared to be independent of the PCB concentration (5.8 and 11.6 micrograms per liter) used. Heat-killed cells sorbed significantly more PCB than live particles. In desorption experiments, most of the PCB leached from the particles within 5 days when dialyzed against PCB-free water. The water lost PCB more rapidly than the particles. The ratio of PCB sorbed to particles to that in an equal volume of water averaged 20,000. (Cassar-FRC)

TRACE METAL FLUXES TO NEARSHORE LONG ISLAND SOUND SEDIMENTS,
New Hampshire Univ., Durham. Dept. of Earth Sciences.
W. B. Lyons, and W. F. Fitzgerald.
Marine Pollution Bulletin, Vol 11, No 6, p 157-161, June, 1980. 1 Fig, 5 Tab, 31 Ref.

Descriptors: *Trace metals, *Marine sediments, *Long Island Sound, *Bottom sediments, Sediment, Metals, Lead, Zinc, Cadmium, Silver, Iron, Manganese, Copper, Fluctuations, Estuaries.

Sediments can act as 'sinks' or 'traps' for trace metals in the coastal marine environment. The concentrations and fluxes of iron, manganese, copper, lead, cadmium, zinc, and silver in the sediments of two nearshore areas in Long Island Sound were investigated. The calculated natural metal fluxes of iron, manganese, zinc, cadmium, and silver for the Mystic River estuary, which is representative of the nearshore sedimentary environment of the eastern part of the Sound, were found to resemble those of the Santa Barbara Basin and the Baltic Sea rather than those of other New England estuaries. The natural fluxes of copper and lead at this site are the lowest ever reported. There was no correlation between increases in dacmium, copper, lead, silver, and zinc in the uppermost sediments and increases in organic carbon. The concentrations of these metals were all strongly correlated with each other, suggesting that they are due to increases in human activity. However, there was no strong relationship between these metals and iron. The calculated fluxes for the Branford Harbor sediments, located offshore from a more industrialized area on the western part of the Sound, resembled those of other New England estuaries. The higher anthropogenic fluxes of metals found at Branford Harbor, as compared to those at the Mystic River site, indicate greater inputs of metals in the western and central portion sections of the Sound due to human activity. Increased trace metal concentrations in the sediments of the Sound proceeding from east to west support this conclusion. Metal concentrations in the sediments at various locations appear to mirror the location of the introduction of the metals into the estuarine system. The highest metal fluxes in the sediments occurred at sites closest to known sources of anthropogenic metal inputs. (Carroll-FRC)

AN INDUSTRIAL AND HAZARDOUS WASTE INVENTORY OF WASHINGTON'S MANUFACTURING INDUSTRIES (1980),
Washington State Dept. of Ecology, Olympia.
D. M. Kruger.
Document WDOE 81-4, February 1981. 28 p. 4 Fig, 12 Tab, 9 Ref, 3 Append.

Descriptors: *Industrial wastes, *Waste management, Inorganic compounds, Waste characteristics, *Landfills, *Hazardous materials, Organic wastes, Toxins, Waste dumps, Solid waste disposal, Waste disposal, Wastes, Wastewater lagoons, *Washington, *Hazardous waste inventory.

The State of Washington is currently developing a statewide hazardous waste management program. Over 500 manufacturing industries, representing 15 percent of Washington industries, were sent an inventory to obtain information on the amount, type, chemical nature (organic or inorganic), and ongoing management practices for treatment, storage, and disposal of industrial and hazardous waste. A total of 350 forms were returned, with 200 industries reporting hazardous waste generation. Inventory information showed that most of Washington's manufacturing waste is inorganic. Nearly 0.4 million tons and 14.3 million gallons of inorganic hazardous waste were generated in 1980. Common waste names reported in the inventory were waste oils, spent solvents, PCB's, heavy metal sludges, paint strippers, pentachlorophenol, metal plating sludges, and spent potliners. Most of the hazardous waste generated in Washington stays in-state. Although a variety of treatment, storage, and disposal methods exist for handling hazardous wastes, in general, little or no treatment technology is employed. Percolation and evaporation lagoons are the primary treatment methods used for liquid wastes. Most solids and sludges are not treated. The primary storage methods for hazardous solids and sludges are piles, while hazardous liquids are stored in pits, ponds, and lagoons. The primary disposal method for solids and sludges is landfilling. Recovery of hazardous wastes, at this time, is the least practiced; less than half the solid hazardous waste is either recycled or reclaimed. (Garrison-Omniplan)

Descriptors: *Pulp and paper industry, Mills, *Wastewater treatment, *Water quality management, Wood waste, Industrial wastewater, Water quality standards, Effluent, Anaerobic bacteria, Bays, Wastewater disposal, Data collection, *Bellingham Bay area, *Washington.

The prime contributor to inner Bellingham Bay's water quality problems, and the focal point of this study, is the pump, paper, and chemical complex operated by the Georgia-Pacific Corporation along the eastern bank of the Whatcom Waterway. This large industrial facility produces, as its main product, approximately 600 tons of sulfite wood pulp per day. Other products from the mill include wastepaper pulp, semichemical pulp, tissue paper, alcohol, lignin byproducts, sulfuric acid, chlorine, and sodium hydroxide. Wastewaters resulting from these activities approach 50 million gallons per day, and in the past have accounted for more than 90 percent of the oxygen-demanding discharges to the inner harbor. The cumulative effect of these wastes and the resulting buildup of anaerobic sludge deposits on the bottom of the Whatcom Waterway resulted in environmental conditions which virtually excluded all but the very lowest and most resistant life forms. These poor conditions existed until May 1979 when Georgia-Pacific constructed a wastewater treatment plant. Data collected during two Bellingham area receiving water surveys document a major improvement in water quality. Completion of the mill's new treatment system in 1979 included the interception of all major mill waste streams. These streams were then re-routed through the mill's aerated lagoon before being discharged to outer Bellingham Bay. Study data from 1980 indicate that the mill's final effluent had a relatively minor negative impact on the quality of the outer bay waters. Environmental quality within this relatively enclosed portion of the bay continues to be somewhat degraded by remaining anaerobic sludge beds. (Garrison-Omniplan)

WILSON CREEK DRAINAGE - SURFACE AND GROUND WATER QUALITY, JULY 1978 TO JULY 1979.
Washington State Dept. of Ecology, Olympia.
Document DOE 80-13, November, 1980. 50 p. 12 Fig, 8 Tab, 13 Ref, 3 Append.

Descriptors: Surface water, Groundwater pollution, Water quality management, Well water, Wastewater treatment, *Urban runoff, *Industrial wastewater, *Agricultural runoff, Irrigation wells, *Water pollution sources, Effluent standards, On-site data collection, Atomic absorption spectroscopy, *Wilson Creek, *Washington, Water pollution effects.

Surface water and groundwater quality were monitored in Wilson Creek drainage in central Washington State from July 1978 through July 1979 to evaluate impacts of irrigated agriculture, urban runoff, municipal and industrial waste disposal, and residential development. While water in domestic wells was found to meet drinking water standards, shallow irrigation wells contain water of poor bacterial quality and are fit for irrigation purposes only. Kittitas sewage treatment plant (STP) effluent was found to be significantly degrading water quality in Cooke Creek with respect to fecal coliforms, nutrients, and aesthetics. Temperature, pH, and dissolved oxygen were generally within Class A standards in Wilson Creek and its tributaries. Return flows from irrigated agriculture were identified as the cause of increased turbidity, solids, nutrient, and bacteria levels in the central and lower drainage. The other point and non-point sources monitored did not appear to impact water quality significantly. The study area encompassed approximately 190 square miles and involved 59 sampling stations. The four surface water parameters measured on site were temperature, pH, specific conductivity, and dissolved oxygen (Winkler-Azide modification). Eleven other parameters were measured in the laboratory, in addition to tests for total coliforms, chlorides, calcium hardness, and total iron. Field parameters measured in the groundwater study included temperature, pH, specific conductivity, and well water levels. Grab samples of water and sediment were collected once each month for determination of lead, mercury, and zinc content by atomic absorption spectrophotometry. (Garrison-Omniplan)

ARE METALS FROM HIGHWAY DUSTFALL HAZARDOUS IN SWIMMING POOLS,
Florida International Univ., Miami. School of Technology.
J. A. Beech.
Journal of Environmental Health, Vol 42, No 6, p 328-331, May/June, 1980. 4 Tab, 18 Ref.

Descriptors: *Swimming pools, *Highway effects, Heavy metals, Recreation facilities, Highways, Roads, Dusts, Metals, Sediments, Water quality.

The possible effect of roadwar dust on the heavy metal content of swimming pool water was investigated. Water from 20 pools alongside busy highways was compared with water from 80 other freshwater pools classified into four groups by pool location and/or type. All samples came from public or commercial open-air pools, originally filled from the Miami municipal water supply. Powdery sediments were noted on the bottom of several pools alongside busy highways. These sediments were also analyzed. Three pool samples exceeded or equaled interim primary drinking water standards for lead or cadmium. Two of these contained 73 and 50 micrograms per liter of lead and one contained 12.1 micrograms of cadmium. Only 20 pool samples contained less than 100 mg/liter of sodium. Sodium ions are added during routine maintenance. Copper content of the sediments varied greatly. Some sediments contained very large amounts of lead. Pool sediments were somewhat higher in metals than are most roadside dusts. No significant differences were found between soluble heavy metal concentrations of water from pools alongside highways and water from other city pools. Until more is known about the properties of these bottom sediments in pools, it is recommended that they be removed from the entire circulating system when the pools are cleaned. (Baker-FRC)

5C. Effects Of Pollution

EFFECT OF CRUDE OIL AND PETROLEUM-DEGRADING MICROORGANISMS ON THE GROWTH OF FRESHWATER AND SOIL PROTOZOA,
Toronto Univ. (Ontario). Dept. of Zoology.
A. Rogerson, and J. Berger.
Journal of General Microbiology, Vol 124, No 1, p 53-59, May, 1981. 3 Fig, 21 Ref.

Descriptors: *Protozoa, *Oil, *Growth rates, *Bacteria, Microorganisms, Water pollution effects, Oil pollution, Microbial degradation, Microbiological studies, *Crude oil.

The ability of a known oil-degrading microflora to support the growth of several common freshwater and soil protozoa was investigated. Also, the protozoa were cultured with emulsified crude oil to study the effects of their directly ingesting oil globules. The following protozoa were cultured either in the presence or in the absence of partially degraded crude oil: Colpidium campylum, Tetrahymena pyriformis, Colpidium colpoda, Colpoda cucullus and Uroleptus. Also, the soil amoeba Naegleria gruberi was cultured. Comparisons were made using the regression coefficient characterizing the slope of the growth curve. The presence of hydrocarbons in the batch culture system did not consistently affect protozoan growth. Protozoan replication was not deterred by the oil droplets observed within the food vacuoles of ciliates. The protozoa most susceptible to reduced growth rates in the presence of emulsified oil were the small pelagic ciliates. In general, there was a slight tendency towards larger protozoa in the presence of oil. (Small-FRC)

ACID RAIN: FACTS AND FALLACIES,
Northeastern Forest Experiment Station, Durham, NH.
J. W. Hornbeck.
Journal of Forestry, Vol 79, No 7, p 438-443, July, 1981. 3 Fig, 45 Ref.

Descriptors: *Acid rain, *Air pollution, *Precipitation, Snowmelt, Rainfall, Acidity, Chemical properties, Industrial wastes, Forests, Ecosystems, Vegetation, Soil environment, Leaching, Water pollution effects.

The sources and effects of acid rain are complex environmental phenomena. Although the major sources are thought to be atmospheric emissions, primarily from urban sources, the exact locations of sources and the mechanisms of transformation of emissions to acid rain are not entirely understood. In the absence of long term records, it is difficult to analyze changes in rainfall acidity and whether this problem is intensifying or spreading. Long range transport of airborne emissions by weather systems has made acid rain a potential threat to aquatic and forest ecosystems in rural areas. Acid rain contains not only substances that donate hydrogen ions, such as nitric and sulfuric acid, but also dissolved ions of common and heavy metals and trace elements. Aquatic ecosystems are the most vulnerable to acid rain in the short run. Acidification of streams and lakes may lead to decreased fish populations and increased concentrations of toxic metals. Acid rain may accelerate the replacement and leaching of basic cations and speed the rate of acidification of soils, particularly shallow, coarse textured forest soils which are already lacking in basic cations. This gradual acidification of the soil could increase leaching of nutrient ions, slow microbiological processes, reduce the variety and populations of soil fauna, and increase the mobility of some toxic elements. Acid rain also appears to be depositing heavy metals on forest soils. Long range effects of acid rain may include reduction of forest productivity and alteration of species composition or diversity. SEDIMENTOLOGICAL AND BIOLOGICAL CHANGES IN THE WINDSOR MUDFLAT, AN AREA OF INDUCED SILTATION,
McMaster Univ., Hamilton (Ontario). Dept. of Geology.
T. R. Turk, M. J. Fisk, R. W. M. Hirtle, and R. K. Yeo.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 9, p 1387-1397, September, 1980. 10 Fig, 2 Tab, 40 Ref.

Descriptors: *Tidal powerplants, *Sedimentation, *Mud flats, *Silting, *Secondary productivity, *Tidal marshes, Tidal flats, Water resources development, Aquatic productivity, Environmental effects, Sediments, Clams, Polychaetes, Amphipods, Ecological effects, Windsor, *Nova Scotia.

The effect of rapid sedimentation on the sedimentological and biological properties of an intertidal mudflat was examined at the causeway-formed mudflat at Windsor, Nova Scotia. The sediments on the Windsor mudflat have occurred as a result of construction of a tidal power dam. The Windsor mudflat is characterized by high water levels, small grain sizes and high levels of organic carbon. The amphipod, Corophium volutator and the clam, Macoma balthica are less abundant in the study site than in surrounding mudflats. The polychaete, Heteromastus filiformis is very abundant at Windsor, while M. balthica grows faster and has a shorter lifespan. However, the weight of the Windsor clams increases more slowly with increasing shell size, probably in response to the greater fluidity of Windsor sediments. These findings suggest that the secondary productivity of Corophium and Macoma could be reduced by about 66% for another decade in existing Minas Basin mudflats. (Geiger-FRC)

RESIDUES IN CUTTHROAT TROUT (SALMO CLARKI) AND CALIFORNIA NEWTS (TARICHIA TOROSA) FROM A LAKE TREATED WITH TECHNICAL CHLORDANE,
Simon Fraser University, Burnaby (British Columbia). Dept. of Biological Sciences.
L. J. Albright, P. C. Oloffs, and S. Y. Szeto.
Journal of Environmental Science and Health, Part B, Vol 15, No 4, p 333-349, 1980. 4 Tab, 13 Ref.

Descriptors: *Chlorinated hydrocarbons, *Residual chlorine, Water pollution, Lake sediments, *Chlordane, Sediments, *Trout, Fish, Salamanders, Amphibians, Cutthroat trout.

Laboratory studies with chlordane and other chlorinated hydrocarbons showed that these compounds were not metabolized in water but, except for lindane, were readily partitioned into the sediments where some metabolism occurred. A subsequent whole-lake study, conducted to extend these laboratory investigations, involved treatment of a lake with about 10 parts per billion of technical chlordane. The uptake of chlordane residues from the lake water and sediment and their metabolism by two macroorganisms was investigated using the California newt, Tarichia torosa, which lives closely associated with the sediment, and the cutthroat trout, Salmo clarki. The newts were collected at 14, 279, 451, and 1,036 days after the water was treated, while the trout were collected at 93, 279, 421, and 1,014 days. Both of the organisms had residue concentrations in their bodies and livers which far exceeded those in their habitat at the first sampling. These first residue concentrations resembled that of technical chlordane, except for heptachlor, which was quantitatively epoxidized in newts after 14 days. Some heptachlor was still present in trout at 93 days. Concentrations of total chlordane in body tissues of both species declined more than 98% by the final sampling. Trans-nonachlor was the most persistent constituent of technical chlordane, accounting for about 50% of the total chlordane in the specimens collected last. Although the chlordane rapidly disappeared from the water into the sediment, the concentrations of total chlordane in the bodies of newts and trout after the samplings taken at 279 days were very similar, suggesting that the newt metabolizes and eliminates chlordane residues more effectively than the cutthroat trout. Both species were found to produce oxychlordane, probably from gamma-chlordane. (Carroll-FRC)

EFFECT OF TEMPERATURE ON MINERALIZATION BY HETEROTROPHIC BACTERIA,
Rensselaer Polytechnic Inst., Troy, NY. Dept. of Biology.
D. L. Tison, and D. H. Pope.
Applied and Environmental Microbiology, Vol 39, No 3, p 584-587, March, 1980. 4 Fig, 9 Ref.

Descriptors: *Thermal pollution, *Bacteria, Heated water, *Temperature effects, Waste heat, Thermal powerplants, Thermal stress, Water pollution effects, Thermal water, Algae.

The results of shifts in temperature on the percentage of substrate mineralized (% Min) by pure cultures of psychrotrophic, mesophilic, and thermophilic bacteria and by naturally occurring microbial communities were studied. The possibility that changes in the % Min may be an indication of stress in microbial communities is discussed. Pure cultures of the bacteria Pseudomonas fluorescens (a psychrotroph), Escherichia coli (a mesophile) and SRL 261 (a thermophile) were shifted away from temperatures to which they were adapted. At this point the % Min increased. The increase was noticeably larger for larger temperature shifts. When natural heterotrophic bacterial populations from sediments of Lake George, New York were subjected to temperature shifts similar responses were noted. The same response was found when a thermophilic algal-bacterial mat community at the Savannah River Plant in Aiken, South Carolina was subjected to temperature shifts. It is suggested that an increase in the % Min may be an indication of thermal stress in bacterial populations. (Baker-FRC)

SURVIVAL OF HUMAN ENTEROVIRUSES IN THE HAWAIIAN OCEAN ENVIRONMENT: EVIDENCE FOR VIRUS-INACTIVATING MICROORGANISMS,
Hawaii Univ., Honolulu. Water Resources Research Center.
R. S. Fujioka, P. C. Loh, and L. S. Lau.
Applied and Environmental Microbiology, Vol 39, No 6, p 1105-1110, June, 1980. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *Seawater, *Enteroviruses, Hawaiian Ocean, Viruses, Temperature effects, Poliovirus, Nutrients, Antibiotics, Microorganisms, *Hawaii, Oahu.

This report describes the stability of human enteroviruses in the seawaters surrounding Oahu, the major island in the state of Hawaii, and characterizes the virus-inactivating agents present in these waters. The time required for a 90% reduction of poliovirus type 1 at 24 degrees C ranged from 24 to 48 hr. Complete inactivation occurred within 72 to 96 hr. A virus-inactivating agent(s) of a microbiological nature was found in both the clean and sewage-polluted seawaters, but not in fresh, mountain stream waters. Antiviral activity disappeared when the seawater samples were subjected to boiling, autoclaving, or filtration through a 0.22- or 0.45-micrometers, but not a 1.0 micrometer membrane filter. The concept that the antiviral activity of the seawater was related to the growth activities of microorganisms was corroborated by the observed effects of added nutrients, a lower temperature of incubation, and the presence of certain antibiotics. Other enteric viruses, such as coxsackie virus B-4 and echo virus-7, were also shown to be similarly inactivated in seawater. (Baker-FRC)

TOXICITIES OF PARAQUAT AND DIQUAT HERBICIDES TO FRESHWATER COPEPODS (DIAPTOMUS SP. AND EUCYCLOPS SP.),
Southern Univ., Baton Rouge. LA. Dept. of Biological Sciences.
S. M. Naqvi, T-S. Leung, and N. Z. Naqvi.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 6, p 918-920, 1980. 2 Tab, 12 Ref.

Descriptors: *Paraquat, *Diquat, *Copepods, *Herbicides, Toxicity, Mortality, Crustaceans, Invertebrates, Water pollution effects, *Aquatic animals, Zooplankton.

Zooplankton were collected from a natural lake with a plankton net. Copepods were separated out by concentrating the sample and removing the upper portion containing the aggregated copepods. Freshwater copepods (Diaptomus sp. and Eucyclops sp.) were exposed to various concentrations (0 to 140 ppm) of the herbicides diquat and paraquat for 24 and 48 hours. LC50 results in ppm were: diquat, 74 at 24 hours, 19 at 48 hours; paraquat, 10 at 24 hours, 5.3 at 48 hours. Mortalities of 98-100% were observed at concentrations of 140 ppm diquat and 100 ppm paraquat in 24 hours and 60 ppm diquat and 30 ppm paraquat in 48 hours. The copepods were slightly more tolerant to these herbicides than cladocerans; however, copepods mortality in aquatic ecosystems due to excessive use of diquat and paraquat cannot be ruled out. (Cassar-FRC)

TOXICITY OF FIVE FOREST INSECTICIDES TO CUTTHROAT TROUT AND TWO SPECIES OF AQUATIC INVERTEBRATES,
Columbia National Fisheries Research Lab., MO.
D. F. Woodward, and W. L. Mauck.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 6, p 846-853, 1980. 3 Tab, 13 Ref.

Descriptors: *Fish, *Insecticides, *Invertebrates, Aquatic life, Toxicity, *Trout, Water pollution effects, Pesticides, Carbamate pesticides, Organophosphorus pesticides, Acephate, Fenitrothion, Trichlorofon, Aminocarb, Carbaryl, *Toxicity.

The toxicity of five forest insecticides was determined for cutthroat trout obtained from the Jack-

son Wyoming National Fish Hatchery and aquatic invertebrates, stonefly naiads from The Snake River and amphipods collected from small springs. The 96-hour LC50s for trout (Salmo clarki) in 12 degrees C soft water at pH 7.5 were (in micrograms per liter): acetate 100,000; aminocarb 28,000; carbaryl 3,950; fenitrothion 2,880; and trichlorofon 1,680. For amphipods (Gammarus pseudolimnaeus) the 96-hour LC50 were (in micrograms per liter): acephate 25,000; aminocarb 1,000-2,200; carbaryl 7-13; fenitrothion 4.3-5.6; and trichlorofon 52-108. In stoneflies (Pteronarcella badia) the 96-hour LC 50s (in micrograms per liter) were: acephate 6,400-21,200; aminocarb 26-28; carbaryl 11-29; fenitrothion 5.1-7.2; and trichlorofon 5.3-100. It is important to note that toxicity of some insecticides varies significantly (by as much as 300-fold) when they are formulated and applied in water of different pH, hardness, or temperatures. All five insecticides, excluding aminocarb, appear safe to cutthroat trout at pH 7.5 or less at normal formulation and application rates. The aquatic invertebrates are much more sensitive to the toxicants. Acephate is the safest forest insecticide to both trout and invertebrates. However, a 2 lb per acre application rate has shown evidence of cholinesterase inhibition in songbirds. (Cassar-FRC)

ASSESSMENT OF THERMAL DISCHARGES ON ZOOPLANKTON IN CONOWINGO POND, PENNSYLVANIA,
Radiation Management Corp., Drumore, PA. Muddy Run Ecological Lab.
D. Mathur, T. W. Robbins, and E. J. Purdy, Jr.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 6, p 937-944, June, 1980. 4 Fig, 5 Tab, 13 Ref.

Descriptors: *Zooplankton, *Thermal pollution, *Statistical analysis, Heated water, Temperature effects, Powerplants, Mathematical studies, Conowingo Pond, Pennsylvania.

Analysis of covariance was used to separate natural variations in zooplankton from those caused by power station operation. The covariants were: density of zooplankton at control station, ambient water temperature, and average daily river flows. The assessment was made at Conowingo Pond, a 35.8 km sq impoundment on the lower Susquehanna River which is part of the Peach Bottom Atomic Power Station, a once-through cooling system. Some of the problems associated with using the ratio of density at the control station to the density at an affected station to adjust for ambient variations were overcome using the convariance technique. Significant differences were found in adjusted preoperational and postoperational means, but these were not attributable to station operation. Multiple regression analysis indicated that an increase in zooplankton production could result from the addition of heated water when river flows were less than 280 cu m/sec. Temperature differences from ambient averaged 10C in winter and 8C in summer. (Small-FRC)
W82-00592

EFFECT OF METALS ON THE BIOMASS PRODUCTION KINETICS OF FRESHWATER COPEPODS,
Canada Center for Inland Waters, Burlington (Ontario).
U. Borgmann, R. Cove, and C. Loveridge.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 4, p 567-575, April, 1980. 5 Fig, 11 Tab, 12 Ref.

Descriptors: *Water pollution effects, *Heavy metals, *Copepods, *Toxicity, Cadmium, Copper, Mercury, Lead, Arsenic, Biomass, Aquatic productivity, Canals, Fluctuations, Seasonal variation, Crustaceans, Mathematical studies.

The effects of cadmium (Cd), copper (Cu), mercury (Hg), lead (Pb), and arsenic (As) on the kinetics of in situ copepod production in the Burlington Canal were examined under static conditions. Nauplii were collected and exposed for two weeks to various concentrations of the metals. Biomass growth rate, mortality rate, cohort biomass growth rate and recoverable metal concentrations were calculated and subjected to mathematical analysis. Results showed seasonal cycles in toxicity for all of the metals except As. Pb toxicity was associated with the ash-free dry weight of the seston, but the fluctuations in Cd, Cu and Hg toxicity could not be explained. Metal toxicity to copepods and daphnids is often more similar in the chronic form than in the acute form. Mathematical relationships between metal levels and growth and mortality rates are presented along with a method for determining sublethal metal concentrations. (Geiger-FRC)

INSECT COMMUNITY STRUCTURE AS AN INDEX OF HEAVY-METAL POLLUTION IN LOTIC ECOSYSTEMS,
Miami Univ., Oxford, OH. Dept. of Zoology.
R. W. Winner, M. W. Boesel, and M. P. Farrell.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 4, p 647-655, April, 1980. 2 Fig, 6 Tab, 28 Ref.

Descriptors: *Heavy metals, *Chironomids, *Stream pollution index, Copper, Chromium, Zinc, Aquatic insects, Caddisflies, Mayflies, Midges, Water pollution effects, Aquatic populations, Bioindicators, Macroinvertebrates, *Lotic environment, Insects, Ecosystems.

Measurements of macroinvertebrate populations in two streams of southwestern Ohio suggest that community structure shows a predictable, graded response to pollution by heavy metals. In heavily polluted regions of both streams, only chironomids and tubificid worms survived in rock rubble and riffle sections. Midge larvae predominated in the most polluted areas. The correlation coefficient for percentage of chironomids in relation to copper levels was +0.93. The lowest changes in coefficient of variation (CV) were found at the most polluted stations and increased along a gradient of decreasing metal levels. The number of chironomid species increased as metal pollution levels decreased. Caddisflies were numerically important at points of intermediate pollution along both streams, while mayflies were found only at areas of very low pollution. The percentage of chironomids present in lotic water samples is proposed as a useful index of stream pollution by heavy metals. (Geiger-FRC)

J. F. Stara, D. Kello, and P. Durkin.
Environmental Health Perspectives, Vol 34, p 145-158, February 1980. 1 Fig, 7 Tab, 88 Ref.

Descriptors: *Human diseases, *Water pollution, Natural waters, *Chemical wastes, Water quality, Carcinogens, Mutagens, Teratogens, Pharmacokinetics, Risks, Public health, Hazardous materials.

The development of ambient water criteria to protect human health is the focus of this paper. Both human and aquatic health assessments involve extrapolating results of observable responses in test species to projected or acceptable levels in the species of concern. Certain practical differences exist between human and aquatic risk assessment. Human health hazard assessment attempts to convert a risk from various mammalian species to only a single species. Aquatic hazard assessment is concerned with the effect of xenobiotic stress in aquatic communities, groups of species interacting by mechanisms which are neither readily quantified nor clearly understood. Information on sources of exposure, pharmacokinetics, and adverse effects must be carefully evaluated. Source data is essential to determine the contribution of exposure from water relative to all other sources. Pharmacokinetic data allow extrapolation and characterization of the mode of toxic action. Toxic effects information includes data on acute, subchronic and chronic toxicity, mutagenicity, teratogenicity, and carcinogenicity. A distinction must be made between threshold and nonthreshold effects. For carcinogens and mutagens criteria are calculated by postulating an acceptable increased level of risk and using extrapolation models to estimate the dose which would result in these increased levels of risk. For other chemicals, thresholds are assumed and criteria are calculated by deriving acceptable daily intakes. (Baker-FRC)

FACTOR ANALYSIS OF THE IMPACT OF THE ENVIRONMENT ON MICROBIAL COMMUNITIES IN THE TVARMINNE AREA, SOUTHERN COAST OF FINLAND,
Zoological Station, Tvarminne (Finland).
P. Vaatanen.
Applied and Environmental Microbiology, Vol 40, No 1, p 55-61, July, 1980. 2 Tab, 22 Ref.

Descriptors: *Microbial studies, *Environmental effects, Populations, Temperature effects, Wind, Seasonal variations, *Finland, Coasts, Estuarine environments, Brackish water, Seawater, Microorganisms, Rainfall, Coliforms, Wastewater outfalls, Effluents, Bacteria.

Data obtained regarding 10 environmental parameters and 16 microbiological parameters at a sampling station on the Tvarminne Archipelago, Finland, had been subjected to regression analysis in a previous study. In the present study, the correlations between the parameters were factorized using the principal axis solution, and eight of the factors of apparently greatest importance were rotated by the varimax method for the total data and the data for the open-water period. The eight factors selected were characterized by different loadings for water temperature, salinity, ice cover, organic and

humic matter, microbial counts, transparency, microbial respiration, wind vectors, and rainfall. All of the microbiological parameters aside from H2S producers, proteolytic bacteria, enterococci and yeasts are mainly loaded in one factor. The factors dealing with freshwater outflows cover 50-69% of the variance of fluorescent pseudomonads, bacterial spores, and fecal coliforms. The water temperature factor explains most of the variance of direct counts. A third factor, vernal phytoplankton bloom, not identified by regression analysis, explains most of the variance of the respiration parameters. These three factors, plus the periods before and after the bloom, covered about 90% of the factor variance in the populations and also the major part of the variance of most microbiological parameters. The west winds, summer rains, and early winter factors did not contribute much to the factor variances, but the parameters contributing to them are still needed for satisfactory interpretation of the factors. Although much of the information provided by factor analysis was the same as that of regression analysis, the environmental processes affecting microbes were easier to identify with the factor analysis than with regression analysis. ANNUAL SUCCESSION OF PHYTOPLANKTON IN ONE HEATED POND IN CENTRAL FINLAND,
Jyvaeskylae Univ. (Finland). Dept. of Biology.
P. Eloranta.
Acta Hydrobiologica, Vol 22, No 4, p 421-438, 1980. 10 Fig, 4 Tab, 13 Ref.

Descriptors: *Phytoplankton, *Cooling ponds, *Seasonal variation, Cooling water, *Temperature effects, Thermal pollution, Water quality, Primary productivity, Biomass, *Finland.

Seasonal fluctuations of phytoplankton biomass and the structure of communities were determined in a pond used to cool one small thermal power plant. The following were monitored: water quality, primary production in situ and in vitro in different temperatures, periphyton on artificial substrates, and zooplankton. The phytoplankton reached a maximum in March of 10.3 gm/cu m, primarily comprising cryptophytes and Asterionella gracillima Heib. The autumn maximum of 11.2 g/cu m was in September and was made up of Cyclotella meneghiniana Kutz. Green algae were dominant in spring and summer. The biomass minimum in the darkest winter season was less than 0.2 g/cu m. The chlorophyll alpha concentration of the phytoplankton fresh weight biomass averaged 0.34%. The Shannon diversity was calculated with natural logarithms, and on the basis of each species amounted to 2.5 to 2.9 in summer and 2.7 to 2.8 in winter. There was no significant correlation between Shannon diversity and the logarithm of the phytoplankton biomass. (Small-FRC)

EFFECT OF OTTER PRAWN TRAWLING ON THE MACROBENTHOS OF A SANDY SUBSTRATUM IN A NEW SOUTH WALES ESTUARY,
New South Wales State Fisheries, Sidney (Australia).
P. J. Gibbs, A. J. Collins, and L. C. Collett.
Australian Journal of Marine and Freshwater Research, Vol 31, No 4, p 509-516, 1980. 5 Fig, 3 Tab, 19 Ref.

Descriptors: *Estuarine environment, *Benthic environment, *Trawling, Benthos, Estuaries, Environmental effects, *Ecological effects, Substrates, Benthic fauna, Sediments, Crustaceans, Fishing industry, New South Wales, *Australia.

Recreational fishermen along the New South Wales coast in Australia have made persistent claims that estuarine otter prawn trawling by commercial fishermen kills benthic organisms, depriving fish species of their food source. This study made a quantitative assessment of the effect of commercial prawn trawling in New South Wales on the macrobenthos of the trawl grounds and made a visual assessment of the operation of commercial nets and otter boards underwater. Macrobenthos at three treatment sites and one control site were sampled on three occasions: before and after intensive trawling, prior to the opening of the commercial prawning season, and at the close of the commercial prawning season. Divers made underwater observations of the otter trawl nets in operation. Numerical clustering techniques were used as a preliminary step to statistical comparisons of the number of individuals, number of species, and species diversity at the four sites. The underwater observations revealed that the effect on the sea bottom and the macrobenthos was minimal when the prawn trawls were operating efficiently. Very little sand was disturbed and the sea bottom appeared only slightly marked by the trawl's passage after repeated trawls. The differences between sites demonstrated by the classificatory analysis and community statistics were thought to be due to the patchiness in distribution generally associated with benthic animals and differences in sediment types at the sites, rather than with the trawling. It was concluded that the otter prawn trawling, as conducted in most estuaries in New South Wales, causes no detectable alterations in the macrobenthic fauna of the trawl grounds. (Carroll-FRC)

BACTERIAL DNA REPAIR ASSAY OF SELECTED COMPOUNDS IN PULP AND PAPER MILL EFFLUENTS,
International Paper Co., Tuxedo Park, NY.
V. J. Boyle, and C. A. Simpson.
Tappi, Vol 63, No 10, p 127-130, October, 1980. 4 Fig, 1 Tab, 14 Ref.

Descriptors: *Pulp and paper industry, *Bacteria, *Mutagenesis, Water pollution effects, Effluents, Toxicity, Organic compounds.

Compounds commonly found in pulp and paper mill effluents were evaluated using the DNA Repair Test, recommended in proposed EPA guidelines. None of the chemicals--abietic acid, trichloroguaiscol, tetrachloroguaiacol, dichlorostearic acid, and epoxystearic acid--showed selective killing of the DNA polymerase-deficient (Pol A-) strain of E. coli at concentrations of 50 to 200 micrograms per disk (100-600 times more concentrated than in papermill final effluents). Nalidixic acid was used as a positive control. Results show that these compounds do not have the potential for the alteration of genetic material as assessed by the DNA Repair Test. (Cassar-FRC)

RECEIVING STREAM FISHERIES STUDIES RELATIVE TO SECONDARY TREATED PULP AND PAPER MILL EFFLUENTS,
Consolidated Papers, Inc., Wisconsin Rapids, WI.
J. D. Weinbauer, D. A. Thiel, V. W. Kaczynski, and C. S. Martin.
Tappi, Vol 63, No 10, p 121-125, October, 1980. 4 Fig, 5 Tab, 11 Ref.

Descriptors: *Pulp and paper industry, *Water pollution control, *Fisheries, Aquatic animals, *Water pollution effects, Fish, Effluents, Wisconsin River, Invertebrates, Benthic fauna, Pike, Water pollution prevention, Ecological effects, Wastewater treatment, Industrial wastes, Organoleptic properties, Taste.

A 70-mile section of the Wisconsin River receiving treated wastes from eight paper mills at five outfalls was the site of a biological study on fish and invertebrate populations. The walleye pike (Stizostedion vitreum) population appeared healthy, as determined by age structure, growth rates, and condition factors. A creel survey of 2028 fishermen indicated that 47.8% felt that fishing had improved over the last few years and 22.2% thought it had not improved. Flavor of the fish was designated excellent by five percent of the fishermen, good by 36%, acceptable by 46%, and poor by 13%. Walleye filets collected at four sites were evaluated by an 18-member flavor test board. The Wisconsin River fish, especially those upstream from the paper mill effluents, had more flavor impairment than control Canadian fish. Evidently, effluents and nonpoint source pollution upstream of the paper mills had more adverse affect on fish flavor than did effluents from the mills. The fish survey identified 1594 fish representing 24 species. Macroinvertebrate species have shown a clear shift from pollution-tolerant species to pollution-intolerant species over the course of the study, which has been conducted annually since 1962. These improvements in biological and water quality status correspond with construction of effluent treatment facilities at the paper mills during the 1970's. (Cassar-FRC)

THE CHANGING STATUS OF REEDSWAMP IN THE NORFOLK BROADS,
Institute of Terrestrial Ecology, Huntingdon (England). Monks Wood Experimental Station.
L. A. Boorman, and R. M. Fuller.
Journal of Applied Ecology, Vol 18, No 1, p 241-269, April, 1981. 7 Fig, 8 Tab, 67 Ref.

Descriptors: *Wetlands, *Vegetation, *Distribution patterns, Swamps, Marshes, *Reedswamp, Rodents, Coypus, Geese, Eutrophication, Grazing, Norfolk Broads, Succession, Water pollution effects, Ecological effects, Lakes, *England.

Changes in the distribution and area of reedswamp (vegetation of various tall immersive graminoids growing where the normal summer water table is above the substratum) from 1880 to the present were documented by Ordnance Survey maps and aerial photographs of the Norfolk Broads. Between 1880 and 1905 reedswamp increased from 216.5 ha to 244.6 ha. Starting in 1905 the reedswamp area decreased steadily to the present 1977 level of 49.2 ha. Prior to 1946, losses were from succession to fern; after 1946, from regression to open water. A major factor in the decline of the reedswamp was grazing by the coypu (Myocaster coypus Molina), a large South American wetland rodent which escaped from fur farms by 1936 and became well established during the 1940's. The population reached a height of about 70,000 in 1962 and presently numbers about 15,000. Feral geese are now actively limiting reedswamp in some areas. Eutrophication appeared to have no direct effects on reedswamp, but increased sedimentation rates can make the reeds, especially the shoots, more available for grazing. Neither soil type or boat traffic were responsible for the reedswamp changes. (Cassar-FRC)

1980 ANNUAL REPORT, COMMITTEE ON THE ASSESSMENT OF HUMAN HEALTH EFFECTS OF GREAT LAKES WATER QUALITY,
International Joint Commission-United States and Canada, Windsor (Ontario).
1980. 34 p. 3 Tab, 11 Ref.

Descriptors: *Lakes, *Toxicity, *Water quality, *Hazardous materials, *Viruses, Epidemiology, Fish populations, Fish diseases, Aquatic populations, Enteroviruses, Toxins, *Great Lakes.

This report summarizes the 1979-80 activities of the Committee on the Assessment of Human Health Effects of Great Lakes Water Quality. High priority was placed on evaluating the health hazards of chemicals identified in the Great Lakes ecosystem. Also investigated were viruses in the Great Lakes, the development of compatible cancer registries within the Great Lakes Basin, and levels of contaminants in fish. The committee attempted a study of the health hazards of 381 compounds but found that toxicological and exposure data on the chemicals were insufficient for a meaningful evaluation. Additional toxicology and exposure studies of potentially hazardous chemicals are recommended. Results of an investigation of enteric viruses indicated that water quality standards for Great Lakes water are successfully preventing these viruses from being spread via the public water supply. However, the development of more sensitive indicators of the presence of viruses is recommended, as well as better data on the relationship between water treatment processes and the fate of water-borne viruses. The Committee also recommended that: (1) additional fish surveillance studies be carried out to assess 'real time'

exposures of man, and to assess the effectiveness of contaminant control strategies; and (2) a workshop be held on the compatibility of Great Lakes Basin cancer registries, as a prelude to a proposed cancer morbidity and mortality survey of the countries bordering Lake Ontario. Also suggested is a workshop on the interaction of toxic chemicals in the Great Lakes ecosystem. (Garrison-Omniplan)

1980 ANNUAL REPORT - A PERSPECTIVE ON THE PROBLEM OF HAZARDOUS SUBSTANCES IN THE GREAT LAKES BASIN ECOSYSTEM,
International Joint Commission-United States and Canada, Windsor (Ontario).
November, 1980. 70 p. 10 Tab, 20 Ref, 1 Append.

Descriptors: *Lake basins, *Contaminants, *Waste water disposal, *Chemical wastes, *Polychlorinated byphenyls, Eutrophication, Halogens, Residual chlorines, Sediments, Sludge, Aquatic populations, Human populations, Suspended solids, Trace metals, Potable water, Chlorine, *Great Lakes basin, Ecosystems.

The infusion of synthetic industrial chemicals has increased exponentially in the Great Lakes ecosystem, particularly in the last 40 years. Some of these chemicals may be toxic. This report discusses these substances relative to biological and human health effects, transport and fate, sources, and control alternatives, and presents a plan for attacking the problems. Effects on human health are often not readily distinguishable; those on aquatic life are more easily seen. Two main sources of human exposure are through drinking water and eating fish. No conclusions have been drawn concerning the health effects of the water quality. One study examined the correlation between PCB residues in Lake Michigan fish and concentrations of PCBs in the blood of those eating the fish. Higher levels were found in those eating large amounts of fish. Hazardous substances in large lakes, such as DDT, dieldrin, mirex, PCBs, phthalates, and mercury, are persistent in the water, sediment, and biota and will be widely dispersed through the lakes. Hazardous substances enter the Great Lakes through emissions to the atmosphere, industrial and municipal wastewater discharges, urban and rural land runoff, and other sources such as spills and leaching from solid waste disposal sites. Recommendations to reduce the problem of hazardous substances include reuse and treatment technologies, reducing the loss or use of stubstance that enter the air or water effluents, identifying high-exposure populations, establishing tolerance levels for toxic substances, and centralizing an information system for data on hazardous substances. (Atkins-Omniplan)

1980 REPORT ON GREAT LAKES WATER QUALITY - APPENDIX,
International Joint Commission-United States and Canada, Windsor (Ontario).
November 12, 1980. 82 p. 14 Fig, 17 Tab.

Descriptors: *Lake rehabilitation, *Eutrophic lakes, *Water quality, *Phosphorus removal, *Algal growth, Algal blooms, Fish populations, Fish conservation, Aquatic populations, Fish diseases, Aquatic environment, Water quality data, *Great Lakes ecosystem.

This appendix was developed to assist the Great Lakes Water Quality Board in preparing its report to the International Joint Commission. Water quality status in the Great Lakes ecosystem is presented with a review of municipal phosphorus control programs. Also included is a brief summary of the development and implementation of data quality assurance programs with specific reference to interlaboratory comparisons. Municipal phosphorus loads are presented on a lake-by-lake basis. Municipal treatment plants are ranked according to the difference between their actual annual phosphorus load and their estimated load at an effluent phosphorus concentration of 1 milligram per liter. A special section on Aquatic Ecosystem Quality reviews the progress in eutrophication control and the decreased residue levels of contaminants observed in several fish species in the lower lakes as well as in gull eggs collected throughout the basin. PCB levels in gull eggs in Lake Superior have exhibited little change, possibly reflecting the importance of atmospheric inputs. Three new problem areas have been identified in the Great Lakes Basin: Marquette and Munising bathing beaches on Lake Superior, which exceeded state fecal and total coliform objectives, and White Lake on Lake Michigan, which was added to the problem area list because of oganics found in water, sediments, and fish. (Garrison-Omniplan)

ACUTE TOXICITY OF ZINC TO SOME FISHES IN HIGH ALKALINITY WATER,
Illinois State Water Survey, Urbana.
P. Reed, D. Richey, and D. Roseboom.
Illinois Institute of Natural Resources, Circular 142, 1980. 21 p. 4 Fig, 5 Tab, 48 Ref, 2 Append.

Descriptors: *Fish populations, *Toxicity, *Zinc, *Alkaline water, *Fish toxins, Poisons, Catfish, Bluegills, Bass, Hazardous materials, Mud-water interfaces, Alkalinity, Water pollution effects, Water pollution sources.

The alkalinity of lakes and streams in Illinois are variable, with concentrations, as calcium carbonate, generally exceeding 200 mg/l in the northern and central part of the state and often less than 100 mg/l in the southern part. This study documents the acute toxic effects of varying concentrations of zinc on certain fishes native to Illinois. Fourteen-day bioassays were performed with bluegill fry, channel catfish fingerlings, and largemouth bass fingerlings in waters relatively high in the salts of calcium and magnesium, with correspondingly high alkalinity. The levels of total zinc in natural water bodies in Illinois generally do not exceed 0.5 mg/l. Soluble zinc concentrations are usually less than 0.05 mg/l, except in those surface waters that are significantly influenced by urban centers. Elevated concentrations of zinc occur at the mud-water interface, during anaerobic conditions, in Illinois lakes. The concentrations thus far observed are generally two to three times higher than those detected in the overlying waters. The 14-day median tolerance limit at 20 degrees Celsius was 11.0 mg/l soluble zinc for the bluegill, 8.2 mg/l soluble zinc for the channel catfish, and 8.0 mg/l soluble zinc for the largemouth bass. For protection of the fishes investigated, and in compliance with Illinois water pollution regulations, soluble zinc concentrations in Illinois streams having alkalinity and hardness should not exceed 0.8 mg/l. DOES IMPROVED WASTE TREATMENT HAVE DEMONSTRABLE BIOLOGICAL BENEFITS,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Center for Environmental Studies.
H. H. Seagle Jr, A. C. Hendricks, and J. Cairns Jr.
Environmental Management, Vol 4, No 1, p 49-56, January, 1980. 3 Fig, 4 Tab, 22 Ref.

Descriptors: *Textile mill wastes, *Water quality control, *Effluents, Industrial wastes, *Wastewater treatment, Aquatic habitats, Water pollution effects, Water pollution control, Invertebrates, Fish, Zinc, Toxicity, Benthic fauna, Diversity indices, Shenandoah River, *Ecological effects.

Ten benthic surveys and 9 static fish bioassays were conducted since 1972 on the South Fork of the Shenandoah River near the Avtex rayon and polyester fibers plant at Fort Royal, Virginia. Prior to construction of an activated sludge treatment system in February 1974, zinc and BOD5 inputs averaged 239 and 733 kg per day, respectively. The benthic community, especially on the right side of the river, where the effluent was channelized, had low diversity values (0-2.42) and reduced numbers of taxa and organisms compared with the upstream control. A fish bioassay showed that the effluent was acutely toxic at an admixture of 34.5% with river water. While water chemistry and temperature were little affected by the improved waste treatment facilities, levels of Zn and BOD5 were significantly reduced and the aquatic habitat improved. The plant's treated effluent contained 70% less BOD5 and 60% less zinc. In 1974 the effluent was toxic to fish at 80% concentration, but it was more toxic after that. Diversity values for fauna increased to 1.19-3.39. Taxa and numbers of organisms increased. Only during drought conditions in 1976 and 1977 did the improved situation regress. Although the benefits of pollution control were clearly demonstrated, complete recovery of the river is unlikely, particularly in areas where the effluent is channelized and at low flow conditions. THE RELATIONSHIP OF ENVIRONMENTAL EPIDEMIOLOGY TO WATER AND WASTEWATER PLANT OPERATORS,
Oklahoma State Dept. of Health, Oklahoma City.
D. Farley.
Southwest and Texas Water Works Journal, Vol 63, No 3, p 10, 12, June, 1981.

Descriptors: *Epidemiology, *Water pollution effects, *Wastewater treatment, Water treatment, Public health, Toxicity, Legislation, Regulations, Legal aspects, Oklahoma State Department of Health, *Wastewater plant operators, Personnel.

Water and wastewater treatment plant operators should be aware of the potential health effects of each step in the processes. The Oklahoma State Department of Health is attempting to apply the concept of epidemiology to this field. The short term acute effects of pollutants in drinking water or renovated wastewater are quickly handled, but chronic, long term effects may be discerned only by epidemiological analysis. EFFECTS OF HYPOLIMNETIC DISCHARGE ON FISH HEALTH BELOW A RESERVOIR,
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
J. M. Grizzle.
Transactions of the American Fisheries Society, Vol 110, No 1, p 29-43, January, 1981. 1 Fig, 3 Tab, 106 Ref.

Descriptors: *Sublethal effects, *Fish, *Hypolimnion, Thermal stratification, *Thermal pollution, Temperature effects, Trout, Perch, Buford Dam, Georgia, Infection, Pathology, Metals, Reservoirs, *Reservoir releases.

Dams often cause changes in the impounded stream or river which have important effects on their fish populations. The release of anoxic, hypolimnetic waters, which often contain dissolved manganese, iron, ammonia, hydrogen sulfide, and other chemicals, from impoundments may increase the downstream concentrations of these substances. Rainbow trout, brown trout, brook trout, and yellow perch from two locations in the tailwater from the Buford Dam, in Georgia, and trout from a hatchery which used the tailwater as a water supply were examined for infections, lesions, and liver metal concentration. The fish were found to be infected by 9 genera of parasites, 19 bacteria species, and 1 virus species. Many of the fish that did not have bacterial infections were found to have microscopic lesions in the gills, liver, spleen, and trunk kidney. The occurrence of lesions indicating exposure to a toxicant was related to increases in iron and manganese concentrations, but not to copper concentrations. While manganese did not indicate exposure to high levels of these metals. Since the tailwater contained copper, zinc, iron, manganese, and dissolved oxygen concentrations considered possibly harmful to fish, acclimation may have allowed survival of the fish in the river. The release of hypolimnetic water from the impoundment resulted in low pH, low dissolved oxygen concentrations, low oxidation-reduction potential, and high metal concentrations. Water characteristics, acclimation by the fish, and possible synergistic activity make most bioassay data unreliable for the prediction of the toxicity of tailwaters. (Carroll-FRC)

POTENTIAL EUTROPHICATION OF THE RIDEAU RIVER BY AN URBAN DRAINAGE WATERWAY,
MacLaren (J. F.) Ltd., Willowdale (Ontario).
M. H. Habicht, K. Adamowski, and A. C. Middleton.
Canadian Journal of Civil Engineering, Vol 8, No 2, p 165-172, June, 1981. 4 Fig, 8 Tab, 9 Ref.

Descriptors: *Eutrophication, *Predictions, *Water management, Management planning, Bioassay, Chemical properties, Storm water, Dam effects, Environmental effects, Nutrients, Algae, Biomass, *Urban watersheds, Industrial wastes, Lumber industry, *Saw mills.

Agricultural activities and industrialization promote natural nutrient enrichment, nuisance blooms of algae, depletion of dissolved oxygen, increased turbidity, and changes in aquatic communities, which lead to eutrophication. A study of the eutrophication potential of an urban drainage waterway (Saw Mill Creek) on the Rideau River in Ottawa was designed to determine the usefulness of a combination of bioassay and chemical characterization for estimating the eutrophication potential of storm water and to investigate possible effects of two storm water management alternatives on eutrophication potential. Samples were collected from the creek and the river during eight different peak storm flow conditions. Although nutrient concentrations were found to increase during storm flows, peak flow concentrations of total phosphorus and nitrogen averaged only 0.190 and 2.5 milligrams per liter, respectively. Saw Mill Creek had no significant effect on algal growth in the Rideau River at nutrient addition ratios of 5 percent or less, which probably includes most dry weather flows. However, bioassays produced significantly different algal standing biomass at 10 and 20 percent nutrient addition levels, indicating that the creek can have statistically significant effects on the algal growth in the river during peak flow conditions, when both nutrient concentrations and flow ratios are high. Algal bioassays were shown to be a valuable technique in analysis of the eutrophication of a receiving water by urban drainage water. Simulation of alum treatment of the creek using a jar test did not result in significant reductions in algal growth when compared to that at any of the nutrient addition levels. A reduction in the volume of storm flows of the creek could significantly affect algal growth in the river, however. (Carroll-FRC)

CONVERSION OF ABIENOL INTO TETRAHYDROEPIMANOOL BY ANAEROBIC PROCESSES IN WOODROOM DEBARKING EFFLUENT,
British Columbia Research Council, Vancouver.
A. B. McKague, and E. G-H. Lee.
Journal of Chemical Technology and Biotechnology, Vol 30, No 5, p 263-265, 1980. 5 Ref.

Descriptors: *Anaerobic conditions, *Abienol, *Wood wastes, Terpenes, Fish, Toxicity, Chemical reactions, Fate of pollutants, Tetrahydroepimanool, *Fish toxins, Organic compounds, Industrial wastes, Microbial degradation.

During a study of softwood woodroom debarking effluents toxic to fish, a sample was delayed in transit for three weeks. When retrieved and analyzed, this sample contained less than 1 mg per cu dm abienol and 13-epimanool, but contained 12 mg per cu dm of tetrahydroepimanool, which is more toxic to fish than the starting compounds. The conversion was duplicated in the laboratory by anaerobic conversion of abienol in samples of woodroom effluent. Microscopic examination of the effluent indicated the presence of a mixed culture of actively motile bacteria. (Cassar-FRC)

EFFECTS OF THERMAL EFFLUENTS ON COMMUNITIES OF BENTHIC MARINE MACROALGAE,
University of Southern California, Los Angeles.
J. S. Devinny.
Journal of Environmental Management, Vol 11, No 3, p 225-242, November, 1980. 2 Fig, 5 Tab, 39 Ref.

Descriptors: *Algae, *Thermal pollution, *Powerplants, Macrophytes, Benthic flora, Effluents, Marine algae, Humboldt Bay, *California, Punta Banda, Mexico, Plant communities, Species diversity, Species composition, Temperature effects.

Marine benthic macroalgae were studied in three sites with thermal water. Two study areas (Humboldt Bay, northern California, and near Long Beach, southern California) received thermal effluents from powerplants, and the third, Punta Banda, Mexico, had no powerplant discharge but a natural thermal gradient in a shallow bay with restricted circulation. Ordination analysis of the algal communities showed that a 10% change in species composition occurred for each degree of temperature up to 3C, but numbers were not reduced. Temperatures 7C above ambient eliminated large macrophytes. Populations of brown algae were reduced or eliminated, and green algal species were a larger proportion of the community. Temperatures 10C above ambient left ephemeral communities low in diversity. (Cassar-FRC)

Descriptors: *Water pollution, *Industrial wastes, *Benthic fauna, *Streams, Heavy metals, Benthos, Wastewater treatment, Sulfuric acid, Chromium, Flow discharge, Environmental effects, Sediments, Water sampling, Turbidity, *Tannery wastes, Conductivity, Substrates, *Marine, Ecological effects.

The effects of a cattleskin tannery on stream quality and benthic macroinvertebrates in central Maine are discussed. Water quality measurements were made at monthly intervals during the summer months at five locations along a river which receives tannery waste. Sediment samples were collected, and the effects of the effluent and accumulation of heavy metals were determined. A distinct reduction in water and substrate quality was evident in June, coinciding with the period of lowest streamflow. The benthic invertebrate community was affected in two ways. The number of taxa was reduced by 60%, and the diversity and distribution of taxa at the collection sites were altered. The number of invertebrates samples for heavy metals was too small to permit drawing conclusions. However, the concentrations of metals found in those sampled approached lethal levels. Contamination was greatest for chromium. (Titus-FRC)

MACROBENTHOS OF PINE ISLAND BAYOU IN THE BIG THICKET NATIONAL PRESERVE, TEXAS,
Lamar University, Beaumont, TX. Dept. of Biology.
R. G. Darville, and R. C. Harrel.
Hydrobiology, Vol. 69, No 3, p 213-223, March, 1980. 1 Fig, 5 Tab, 27 Ref.

Descriptors: *Water quality, *Benthic fauna, *Streams, *Pine Island, *Texas, Big Thicket National Preserve, Species diversity, Biological communities, Water pollution effects, Seepage, Brines, Oil.

Water quality was generally good at 7 stations on Pine Island and Little Pine Island bayous of southeast Texas, according to surveys conducted June 1977 to May 1978. Seepage of brines from nearby oil fields was revealed by higher Cl and conductivity values at four stations. The higher chloride content (up to 1440 ppm) improved stream conditions by flocculation of suspended solids and reducing turbidity. BOD was relatively low, 0.1-10.4 mg per liter. Dissolved oxygen ranged from 0.8 ppm in small isolated pools to 12.2 ppm. Carbon dioxide concentrations generally decreased downstream. pH was lowest at the upper stations (4.2-7.4) and highest (5.4-7.8) near the sewage effluent outlet. Turbidity ranged from 20 to 395 JTU. Orthophosphates and nitrates were highest near the effluent outfall. The highest chlorophyll a concentration measured was 0.2948 mg per liter. Dominant benthic fauna were oligochaetes (62.3%) and chironomids (22.5%). The intolerant mayfly Hexagenia limbata was found at all stations except below the sewage outfall. The number of taxa found varied from 71 at the station with lowest turbidity to 43 below the effluent discharge. The highest annual diversity, 3.82, was found at the station with lowest turbidity. All other stations had diversity values of 2.57 to 3.09, indicating moderately stressed communities. (Cassar-FRC)

THE EFFECTS OF HEAVY METALS ON MICROBIAL BIOMASS IN SEDIMENTS OF PALESTINE LAKE,
Purdue Univ., Lafayette, IN. Dept. of Bionucleonics.
C. E. Nugent, G. J. Atchison, D. W. Nelson, and A. W. McIntosh.
Hydrogiologia, Vol 70, No 1/2, p 69-73, April, 1980. 2 Fig, 4 Tab, 20 Ref.

Descriptors: *Heavy metals, *Sediments, *Metal finishing wastes, Biomass, Microorganisms, Metals, Zinc, Chromium, Cadmium, *Palestine Lake, Indiana, Lake sediments, Lakes, Water pollution effects, Microbial degradation, Degradation, Organic matter, *Eutrophic lakes.

Palestine Lake, Indiana, a highly eutrophic lake which receives chromium, cadmium, and zinc from an electroplating plant, showed suppression of organic decomposition and low microbial biomass in the most contaminated sediment, averaging metal concentrations (micrograms per g dry weight) of 17,840 Zn, 4380 Cr, and 585 Cd. Adenosine triphosphate (ATP) concentrations and microbial colony numbers on pour plates were used as biomass indicators. The highly contaminated area had 3.7 million mean microbial colonies in 1 g sediment; the less contaminated sites had 27-62 million. ATP concentrations were 2.9 times 10 to the minus 7th power in the highly contaminated area and 4.5-7.6 times 10 to the minus 7th power in the less contaminated sites. (Cassar-FRC)

Canadian Journal of Fisheries and Aquatic Sciences, Vol 37, No 7, p 1175-1183, July, 1980. 4 Fig, 3 Tab, 15 Ref.

Descriptors: *Eutrophication, *Fishkill, *Algal control, *Species composition, *Nitrogen, Nutrients, Nitrate, Algal growth, Biomass, Aquatic productivity, Primary productivity, Ammonium, Cyanophyta, Chlorophyta, Ponds.

The nutrient contents of a small prairie lake and a pond which has experienced seasonal anoxia as a result of collapses of Aphanizomenon flos-aquae blooms were experimentally manipulated to see if changes in phytoplankton composition rather than pesticides could be used to control summerkill. Ammonium, nitrate or both were added to the prairie lake in enclosures and to the whole pond over an 8 to 12-wk period. When nitrogen was added prior to the appearance of A. flos-aquae, the bloom magnitude and species composition of the algae were altered. The biomass of this alga was reduced when low level additions (0.75-1.5 g/cu m/wk) of nitrogen were added after the appearance of cyanophyte blooms. With high nitrogen additions (7-14 g/cu m/wk), cyanophytes disappeared and small chlorophytes and cryptomonads dominated. In the absence of A. flos-aquae, the fishkill did not occur. High additions of nitrogen caused significant nitrate residues in the water. Without nutrient supplements, both the lake and pond returned to heavy A. flos-aquae blooms and fishkills the following summer. (Geiger-FRC)

Descriptors: *Asbestos, *Drinking water, Potable water, *Toxicity, Culturing techniques, Cultures, Carcinogens, Particulate matter.

Six coded samples of particulate matter were provided by the United States Environmental Protection Agency for use in tests designed to assay the toxic potential of the samples through the inhibition of colony-forming efficiency of cultured human embryonic intestine-derived epithelial (I-407) cells. The samples were: (1) particulates filtered from Duluth, Minnesota drinking water, known to contain amphibole crystals, red clay, and biological fragments; (2) particulates from Seattle, Washington drinking water, containing chrysotile asbestos; (3) particulates filtered from San Francisco, California drinking water, containing chrysotile asbestos; (4) a sample of less than 2 micrometer size fraction of taconite tailings prepared by a sedimentation separation procedure; (5) a sample of attapulgite clay, a nonasbestos mineral consisting of fibers of the same or smaller diameter range as chrysotile asbestos; (6) amosite fibers, used to study the effects of ingested asbestos on rats and hamsters. The results of the assay indicated that the most toxic of the samples was amosite. The toxicities of the particulates from drinking water were about 100-fold less than that of amosite. The order of toxicity of the drinking water particulate samples decreased from San Francisco, to Seattle, to Duluth. Samples of attapulgite clay and taconite tailings displayed about half the toxicity of the drinking water particulates. These results indicate that this assay provides a sensitive and accurate method for screening asbestos and asbestiform contamination for potential toxicity. (Baker-FRC)

UPTAKE AND TRANSFER OF THE CHLORINATED HYDROCARBON LINDANE (GAMMA-BHC) IN A LABORATORY FRESHWATER FOOD CHAIN,
Hamburg Univ. (Germany, F.R.) Inst. fuer Hydrobiologie und Fischereiwissenschaft.
P. D. Hansen.
Environmental Pollution, (Series A) Vol 21, No 2, p 97-108, February, 1980. 4 Fig, 14 Ref.

Descriptors: *Lindane, *Food chain, *Accumulation, Daphnia, Algae, Chlorella, Stickleback, *Fish, Insecticides, Pesticides, Fate of pollutants, Adsorption, Chlorinated hydrocarbons.

The uptake, transfer, and accumulation of lindane (gamma-BHC) was studied in a freshwater food chain consisting of Chlorella sp., the primary producer; Daphnia magna, Consumer 1; and the stickleback, Gasterosteus aculeatus, Consumer 2. The algae used had an accumulation factor of 749 from a medium containing 10 micrograms per liter lindane. Total accumulation factors for the other 2 links in the food chain were: Daphnia, 66.8; and fish, 118.6. A model was developed showing the lindane accumulated by each consumer during 50 days feeding in water with 10 micrograms per liter lindane. Adsorption from water was essentially complete within 1 to 3 days while accumulation from food continued to increase. Laboratory Daphnia accumulated far more lindane than free-living Daphnia. The sublethal concentrations of lindane caused irritation and a 50% reduction in reproduction rate in Daphnia. Fish rapidly approached the equilibrium concentration. After 9 days, 67% of the total lindane was found in the fish, with large amounts in gills, stomach, liver, and gut. Female sticklebacks took up more lindane than males; males in breeding condition had an accumulation factor 5.8 times larger than those in normal condition. (Cassar-FRC)

ASSESSMENT OF WATER QUALITY CONDITIONS IN SKAMOKAWA CREEK, WASHINGTON,
Washington State Dept. of Ecology, Olympia.
D. Norton.
Document DOE 81-7, February, 1981. 16 p, 3 Fig, 3 Tab, 20 Ref.

Descriptors: *Water quality standards, *Coliforms, *Streams, *Feces, Cattle, *Bacteria, Contamination, On-site data collections, Benthic environment, Fish populations, Spawning, Dissolved oxygen, Skamokawa basin, *Washington.

A sanitary survey was conducted to determine water quality conditions in the Skamokawa basin, located in Wahkiakum county in Washington. Skamokawa Creek is a small tributary of the lower Columbia River Basin. The creek met all criteria for Class A waters in the state with the exception of fecal coliforms. Skamokawa Creek was in violation of the Class A standard with a median value of 200 organisms per 100 ml with 50 percent of the samples exceeding 200 organisms per 100 ml. The high fecal coliform levels most likely result from the proximity to the creek of older homes, many of which discharge directly into the creek. This proximity prevents adequate buffering between the drain fields of the residences and the creek. In addition, cattle access is virtually unrestricted throughout most of the area. Contamination from dairy cattle could be expected to increase during the rainy season when runoff from adjacent pastures increases. Fourteen sampling stations were established, and water samples were collected for laboratory analysis of fourteen components. Physical and chemical factors analyzed were pH, total alkalinity, specific conductivity, turbidity, total suspended solids, and nutrients. Bacteriological and biological factors were also studied. Skamokawa Creek appears to be quite suitable for fish passage and spawning success, except when very heavy spawning is combined with unusually low dissolved oxygen concentrations. Dissolved oxygen concentrations during the survey were well within the acceptable limits for fish survival. Overall, it appears that the benthic community in Skamokawa Creek has been only slightly to moderately impacted. (Garrison-Omniplan)

CHLORINATED HYDROCARBONS AS A FACTOR IN THE REPRODUCTION AND SURVIVAL OF LAKE TROUT (SALVELINUS NAMAYCUSH) IN LAKE MICHIGAN.
National Marine Fisheries Dervice, Ann Arbor, MI. Great Lakes Fishery Lab.
Technical Papers of the U.S. Fish and Wildlife Service, No 105, 1981. 44 p, 6 Fig, 18 Tab, 136 Ref.

Descriptors: *Trout, *Lake Michigan, *DDE, *Polychlorinated biphenyls, *Toxicity, *Mortality, Growth, Pesticide residues, Metabolism, Chlorinated hydrocarbons, Aroclors, Water pollution effects, Fish behavior, Fish food, Growth stages.

Although lake trout were considered extinct in Lake Michigan by the mid 1950's, control of the sea lamprey and restocking resulted in an abundance of hatchery-produced lake trout in the lake by the early 1970's. However, no naturally produced yearling or older lake trout have been found in the lake. Studies were carried out on the performance and survival of fry hatched from eggs of Lake Michigan lake trout and exposed for 6 months to PCB's (Aroclor 1254) and DDE at concentrations similar to those present in offshore waters and zooplankton (10.0 ng/l PCB's and 1.0 ng/l DDE in water; 1.0 micro g/g PCB's and 0.1 micro g/g DDE in food) and at concentrations 5 and 25 times higher. Cumulative mortality of the fry exposed to simulated Lake Michigan levels of PCB's and DDE for 6 months was 40.7%, nearly twice that of unexposed (control) fry, and mortality at the highest exposure level was 46.5%. Evaluation of the growth, swimming performance, predator avoidance, temperature preference, and me-

tabolism of the fry showed no significant effects attributable to exposure to PCB's and DDE, except for a lowering of preferred temperature at the 25X exposures. Although several factors have undoubtedly contributed to the lack of recruitment of naturally produced lake trout in Lake Michigan, the levels of PCB's and DDE present during the early to mid 1970's were sufficient to significantly reduce survival of any fry produced in the lake and thereby impede restoration of self-sustaining lake trout populations. The added exposure of the fry to other toxic substances known to be present in the lake could have further reduced survival. (Moore-SRC)

HEALTH EFFECTS OF MONOCHLORAMINES IN DRINKING WATER,
Massachusetts Univ., Amherst. Div. of Public Health.
G. S. Moore, E. J. Calabrese, and M. McGee.
Journal of Environmental Science and Health, Part A, Vol 15, No 3, p 239-258, 1980. 3 Tab, 36 Ref.

Descriptors: *Chlorination, *Drinking water, Potable water, Disinfection, Chloramines, Water treatment, Water quality, *Monochloramines.

The possibility that monochloramines in drinking water might alter any of a variety of blood characteristics, including those reflecting oxidant stress, in laboratory mice exposed over a wide range of monochloramine concentrations was investigated. Male A/J mice were randomly allocated to one of seven treatment groups: 200, 100, 50, 25, and 2.5 ppm monochloramine in drinking water plus one group receiving deionized water and one group receiving deionized water with a carbonate-bicarbonate buffer. Exposure continued for 30 days. Significant decreases in water consumption were seen at monochloramine concentrations in excess of 2.5 ppm. No significant treatment-related changes in mortality were seen. With the exception of hematocrit, which rose slightly (possibly due to reduced water intake), none of the blood characteristics indicative of oxidant stress and prehemolytic conditions was significantly affected at any dose level. ASBESTOS CEMENT PIPE AND CANCER IN CONNECTICUT 1955-1974,
Yale Univ., New Haven, CT.
J. W. Meigs, S. D. Walter, J. F. Heston, J. R. Millette, and G. F. Craun.
Journal of Environmental Health, Vol 42, No 4, p 187-191, January/February, 1980. 1 Tab, 18 Ref.

Descriptors: *Pipes, *Asbestos cement, Conveyance structures, Water transport, Public health, *Carcinogens, Epidemiology.

To assess the possible influences of asbestos cement (A/C) pipe use on cancer occurrence in Connecticut, individual town cancer rates were entered into a regression equation as the dependent variable, while asbestos exposure indicators for each town were entered as independent variables. Over 40 years of cancer incidence data were available. For 82 towns in which public water supplies were delivered either partly or wholly through A/C pipe, chrysotile asbestos fibers per liter were measured at the source and in water that had passed through A/C pipe. None of these towns had asbestos values as high as 100,000 fibers/liter in source waters. No consistent patterns of association between A/C pipe and cancer were found. Fairly consistent associations of certain cancer rates with town population density and socioeconomic status were found. Socioeconomic scores of Connecticut towns were negatively associated with stomach cancer but positively associated with male colon cancer. A positive association between length of A/C pipe and incidence of kidney cancer was found for both sexes in the 1955-64 study. Also in the 1955-1964 period, a lack of corrosion control for A/C pipes was correlated with bladder cancer, and a high aggressiveness index of water was correlated with colon cancer. No evidence was seen which would warrant changing current water distribution policies for Connecticut public water due to the use of A/C pipes. (Baker-FRC)

FEEDING ANIMALS ACTIVATED SLUDGE,
S. Beszedits.
Water and Pollution Control, Vol 119, No 4, p 16, 17, 27, April, 1981.

Descriptors: *Domestic animals, *Feeds, *Activated sludge, Amino acids, Proteins, Vitamins, Sludge disposal, Industrial wastes, Recycling, Waste recovery.

Properly prepared activated sludge has been fed to chickens, pigs, cattle and other animals in experimental studies for years. It has a 25-40% protein content and is a rich source of B-vitamins. Municipal sewage sludge has been fed to pigs at levels up to 4% and to chickens at 2.5% with no adverse effects. Sludges from industry vary in protein and vitamin content according to their source. Studies on composition and feeding studies of treated wastes from breweries, slaughterhouses, citrus fruit processing plants, canneries, dairies, and cane molasses distilleries are briefly discussed. FOAM CONTROL IN AERATION TANKS,
Terminal Island Treatment Plant, Los Angeles, CA.
K. L. Ludwig.
Water/Engineering and Management, Vol 128, No 6, p 34, 39, June, 1981.

Descriptors: *Water treatment facilities, *Foaming, *Foam separation, Wastewater treatment, Secondary wastewater treatment, Industrial wastes, Los Angeles.

The Terminal Island Treatment Plant (TITP) is one of the three large wastewater treatment plants operated by the city of Los Angeles and is located in the Los Angeles Harbor area. TITP is designed to provide complete secondary treatment for an average 30 mgd flow of combined domestic and industrial type wastewaters. The plant relies on the sludge process to achieve the desired level of secondary treatment. The plant operates under diurnal conditions. The present flow through this plant is about 60% of the design capacity, with about 45% of the flow being of industrial origin. Problems encountered due to excessive foam accumulation have been numerous. Foam has overflowed aeration tanks and drained into adjacent pipe galleries. This has required extensive cleanup operations. Since the air feed had to be cut due to extensive foaming, expensive chemical oxygen supplements had to be used. Heavy use of the spray system results in misting conditions arising around the aeration tanks, which leads to numerous other problems as well. TITP tested the Koach Foam Splitter under heavy foam conditions for about six weeks. The unit successfully reduced foams; they were destroyed at the rate of two inches of foam depth per hour for an aeration tank 30 feet wide and 300 feet long. Following the testing period, the foam splitter was installed permanently. While the foam was not completely eliminated, it was controlled. (Baker-FRC)

PRESSURE SEWER SYSTEMS,
Los Angeles County Sanitation District, CA.
D. Glasgow.
Water/Engineering and Management, Vol 128, No 6, p 68-70, June, 1981. 2 Fig, 5 Ref.

Descriptors: *Sewer systems, *Wastewater collection, Wastewater treatment, Water conveyance, Design considerations, Pressure head, Hydraulics, Equipment, Pumps, Interceptor sewers, Septic tanks, Septic sludge.

In geographical areas where adverse topographical conditions exist, pressure sewer systems have found increasing application. In 1978 a survey revealed that 60 individual pressure sewer systems were in use. Two major types of pressure sewer systems are the grinder pump system and the septic tank effluent pump system. A third type is the variable gradient system. The grinder pump system consists of a holding tank receiving the sewage directly from the service location and retaining it until enough liquid has accumulated to allow the grinder pump to operate for a 1 or 2 minute cycle. The septic tank effluent system consists of a conventional interceptor or septic tank in which the solid materials discharged from the service user are retained in the tank as either settled sludge or as a floating scum. A pressure sewer is normally designed to flow full at all times. During no-flow periods problems can develop due to grease or solids accumulation. Typically the pressure sewer mains are patterned in either dendriform or grid horizontal layouts. Dendriform layouts theoretically require the least amount of pressure sewer main construction. EMPIRE CONTROLLED BY COMPUTER,
Short-Elliott-Hendrickson, Inc., St. Paul, MN.
D. E. Lund.
Water/Engineering and Management, Vol 128, No 6, p 30-33, June, 1981.

Descriptors: *Water treatment facilities, *Computers, *Wastewater treatment, Tertiary wastewater treatment, Filtration, Sludge, Activated sludge, Effluents, Consolidated facilities, *Minnesota, Empire, Apple Valley, Lakeville, Farmington.

A two-stage activated sludge process followed by tertiary filtration was suggested for the Empire Wastewater Treatment Plant, serving the communities of Apple Valley, Lakeville and Farmington, Minnesota. A central computer system monitors and controls each process and about 98% of the mechanical equipment throughout the treatment facility. The system consists of two identical computers powered by an uninterruptible power supply. Either computer can serve as the primary unit, with the second one continually gathering data and being maintained in a ready status in case of a malfunction by the other. The computer system also provides the plant operators with numerous reports, logs and displays which alert operators of any critical conditions that may develop in the plant. It also creates many operating reports that normally would require a considerable amount of operator time to complete. Tertiary filtration at Empire is obtained with gravity-type dual-media filters for removal of fine suspended materials. The tertiary filters also provide a substantial safeguard in the treatment process. Methane gas produced during the primary sludge and waste activated sludge thickening process is used as fuel in the plant boilers. (Baker-FRC)

MIDWESTERN WASTEWATER CHARACTERISTICS,
Environmental Protection Agency, Chicago, IL.
D. H. Stoltenberg.
Public Works, Vol 111, No 1, p 52-53, January, 1980. 3 Fig, 2 Tab, 6 Ref.

Descriptors: *Wastewater composition, *Municipal wastewater, Wastewater treatment, Biological oxygen demand, Suspended solids, Water treatment facilities, Illinois, Indiana, Ohio, Minnesota, Surveys, Operating policies.

Analyses were conducted of data obtained from operation and maintenance inspection forms completed by personnel from the Environmental Protection Agency or state personnel. Inspections were conducted in 1974-1979; reports were analyzed from 100 municipalities in Illinois, Indiana, Ohio, and Minnesota, with treatment plants serving from 10,000 to more than 100,000 inhabitants. Daily per capita loadings for flow, BOD, and suspended solids were about 40% higher than values reported in standard engineering texts. Statistical analysis produced the following values (mean of 100 plants): flow, 166 gallons per capita per day; BOD5, 0.203 lb per capita per day; and suspended solids, 0.246 lb per capita per day. Comparable data from the literature were: flow, 58-135 gallons per capita per day; BOD5, 0.1-0.2 lb per capita per day; and suspended solids, 0.08-0.23 lb per capita per day. Increased use of garbage grinders may account for the increase in suspended solids loadings. (Cassar-FRC)

A NOTE ON THE FATE OF EL TOR CHOLERA AND OTHER VIBRIOS IN PERCOLATING FILTERS,
Surrey Univ., Guilford (England). Dept. of Microbiology.
R. R. Daniel, and B. J. Lloyd.
Journal of Applied Bacteriology, Vol 48, No 2, p 207-210, April, 1980. 1 Fig, 1 Tab, 4 Ref.

Descriptors: *Human disease, *Percolating filters, *Anaerobic conditions, *Vibrio, Performance evaluation, Wastewater treatment, Public health.

Field results and laboratory experiment results are presented from a study designed to test the ability of Vibrio cholerae El Tor and non-cholera vibrios to grow in anaerobic sewage effluent. Samples of sewage effluent from the anaerobic settling tanks of the Oxfam Sanitation System contained reduced populations of Enterobacteriaceae and small numbers of non-cholera vibrios (NCV's). Samples were passed through percolating filters made of broken honeycomb bricks or zig-zag stakes of corrugated iron. The NCV's multiplied in both filter types. In the laboratory, NCV's were able to multiply in sewage effluent in static culture. Also, Vibrio cholerae El Tor did not multiply in the laboratory but died rapidly. The efficiency of percolating filters may be improved by ensuring an excessively strong liquor and ponding of the liquid. (Small-FRC)

LAND TREATMENT OF MUNICIPAL WASTEWATER IN SMALL COMMUNITIES,
Economics, Statistics, and Cooperatives Service, Washington, DC. Natural Resources Economics Div.
C. E. Young, and D. J. Epp.
American Journal of Agricultural Economics, Vol 62, No 2, p 238-243, May, 1980. 3 Tab, 11 Ref.

Descriptors: *Land disposal, *Municipal wastewater, *Wastewater treatment, Economic aspects, Effluents, Irrigation, Overland flow, Infiltration, Agriculture, Simulation analysis, Crop production, Cost analysis.

Many small communities allocate a substantial portion of their budgets to wastewater treatment. Increasing numbers of small rural communities are being required to provide advanced wastewater treatment in order to meet surface water quality standards. Land treatment of municipal wastewater can meet water quality standards at about half the cost of other advanced treatment alternatives. Irrigation, overland flow, or rapid infiltration can be used to apply wastewater to land for treatment and removal of pollutants. The cost of land application of wastewater (CLAW) simulation model was used to study the design of land application systems. This computer simulation model can be used to design land application systems capable of treating between 0.1 and 100 million gallons of wastewater per day using solid-set irrigation, center pivot irrigation, border strip irrigation, ridge and furrow irrigation, overland flow, and infiltration basins. The model considers preapplication treatment, effluent transmission, wastewater storage, application method, cropping, and recovery of renovated wastewater, if desired. Capital and operating costs are computed and net crop revenue is determined. The choice of crop is a significant factor in the cost of land application facilities, since crops capable of treating smaller amounts of wastewater or irrigation over shorter periods will necessitate facilities for the storage of wastewater. Federal grants for the construction of wastewater treatment facilities can lead to the choice of an option which minimizes local costs without maximizing the amount of wastewater applied. (Carroll-FRC)

SYSTEM FOR OIL AND WATER SEPARATION,
J. Di Perna.
U.S. Patent No 4,203,842, 5 p, 4 Fig, 6 Ref; Official Gazette of the United States Patent Office, Vol 994, No 3, p 987, May 20, 1980.

Descriptors: *Patents, *Oil pollution, *Water pollution treatment, *Separation techniques, Water quality control, Equipment, Oil tankers.

The principal object of the invention is to provide an improved system for oil and water separation when these fluids are intended to be removed from a ship, so that only the water can be dumped back into the sea while the oil is collected in tanks so as not to pollute the sea water. It provides a system for oil and water separation that utilizes a siphon and vacuum means for moving the oil and water mixture instead of employing a pump. The system includes a relatively small, sealed tank upon the deck of the vessel, a hand controlled vent valve on top of the tank, an outlet end of a siphon line entering the tank while an inlet end of the siphon line may run into a collection or other tank, and discharge lines from lower and upper ends of the sealed tank being connected to pumps for discharging oil at the top and water at the bottom. MANAGEMENT TRAINING IS THE KEY TO GOOD OPERATOR PERFORMANCE,
V. W. Langworthy.
Water and Sewage Works, Vol 127, No 4, p 58, April, 1980.

Descriptors: *Management planning, *Training, Administration, Water treatment facilities, *Wastewater facilities, Water distribution.

The Association of Boards of Certification has worked hard to develop compatibility between states for effective intrastate programming of operator performance levels that are acceptable for water and wastewater operations. Standardization of examination questions and formats among the various grades of certification is one area of concern. A program is needed which will encourage the top individuals in this field to aim for increased self-improvement so that situations which arise can be met by persons capable of handling them. Management/supervisory training is currently available, but few are interested in participating in these programs. Some states are now insisting that an applicant for a managerial position in the water and wastewater industry must have some management expertise. Adequate programs with adequate incentives must be accepted nationwide to increase interest in and appreciation of this area of employment. (Baker-FRC)

MIXING TECHNOLOGY REDUCES ENERGY USE,
General Motors Corp., Saginaw. Steering Gear Div.
H. G. Peters, Sr.
Industrial Wastes, Vol 26, No 3, p 26-27, 34, May/June, 1980.

Descriptors: *Industrial wastes, *Energy conservation, *Water treatment facilities, Wastewater treatment, Design criteria, *Oil industry, Oil pollution, Oily water, Oil.

Plant needs called for a wastewater treatment facility that could extract both soluble and insoluble oils and reduce phosphate and metal contaminates to proposed acceptable levels, while requiring the lowest levels of energy consumption possible. API-type separators were installed to remove floating oils and extract settleable solids. However, these did not deal with the soluble oils present, which ranged from 1,000-1,500 ppm, with surges as high as 5,000 ppm. A new facility was needed to handle an immediate treatment load of 1.5 mgd, with a longer-term daily treatment potential of 2.5 mgd and a short term emergency capacity of 5 mgd. The facility must extract soluble as well as insoluble oils, thus eliminating the major disposal problem, and reduce phosphate and metal contaminants to acceptable levels. The final design calls for two API-type oil separators, each of 1,000 Gpm capacity, to mechanically remove floating oils and settleable solids. The secondary treatment consists of a batching operation followed by a pumping system and a flow-splitter feeding dual dissolved air flotation cells (DAF). The tertiary treatment stage consists of two parallel systems, each fed by the two secondary DAF's. All stages of the system are supplied with additives. Wastewater passing through a final DAF is monitored for turbidity. An automatic interlock/reject system prevents the release of any wastewater that does not meet discharge standards. Actual oil in the discharge has ranged from 5 to 20 ppm, versus the 100 ppm code standard. (Baker-FRC)

COLD WEATHER WASTE TREATMENT,
Hoover-NSK Bearing Plant, Ann Arbor, MI.
M. Bitondo.
Industrial Wastes, Vol 26, No 1, p 29, 33, January/February, 1980. 1 Tab.

Descriptors: *Wastewater treatment, *Bacteria, Water treatment facilities, Temperature effects, Cultures, Seasonal variations, Bacterial physiology, Cold regions, Winter, Freezing, *Economic efficiency, *Ann Arbor, Michigan.

Bacterial supplementation was attempted in wastewater treatment facilities in Ann Arbor, Michigan, where the freezing temperatures encountered during the winter season would kill off the bacteria naturally found in sewage, thereby upsetting the bacterial balance needed for efficient wastewater degradation. During the 1978-1979 winter season, the plant's BOD levels were within state limits in spite of prolonged periods of freezing temperatures. During this time DBC Plus bacterial cultures were used in the bioaugmentation program. In this program specially selected and formulated bacteria are added to a sewage treatment plant. Initially relatively large doses of the preparation are added to fully inoculate the system. Application of the bacterial cultures is easy. The operation costs less than $100 per month and has enabled the company to meet state standards without expensive new equipment. (Baker-FRC)
W82-00636

FOAM CONTROL AND DEGRADATION OF NONIONIC DETERGENTS,
Sybron Corp., Salem, VA. Biochemical Div.
P. Spraker, and M. Telepchak.
Industrial Wastes, Vol 26, No 1, p 16-17, 34, January/February, 1980. 1 Fig, 2 Tab, 1 Ref.

Descriptors: *Industrial wastes, *Wastewater treatment, Detergents, Soaps, *Surfactants, *Phenols, Biodegradation, Foaming, Bacteria, Cultures, *Textile mill wastes.

A decision was made to treat textile manufacturing wastewater containing phenols and surfactants with biological methods through the addition of mutant bacterial cultures to a biotower and aerated lagoons. The increased efficiencies of the bacteria produced a system capable of biological oxidation with considerably less aeration, with large reductions obtained in energy consumption and cost. Large quantities of foam were not produced by this system. A full scale biotower was designed to remove 150 mg/liter of phenol from 30,000 Gpd wastewater. The biotower structure contains 1,000 cubic feet of packing and has 6,000 gal reservoir capacity. The recycle rate was 960 Gpm. The biotower began showing reduction of the wastewater after 8 days of operation. COD and phenol content were measured. Average COD reductions were between 58-68% from an initial value of 4,481 mg/liter. Phenol content was reduced 99.4% from an original value of 9.2 to 12.8 mg/liter. Data collected over a year's time showed up to 66% reduction of BOD. Thus the system of mutant bacteria and the biotower has produced a much more efficient system, capable of handling difficult to degrade compounds in a more cost effective manner. (Baker-FRC)
W82-00637

CHEMICAL TREATMENT SOLVES TANNERY WASTE PROBLEMS,
Gunnison Bros. Girard, PA.
M. Giles.
Industrial Wastes, Vol 26, No 2, p 30-31, March/April, 1980. 1 Fig.

Descriptors: *Tannery wastes, *Wastewater treatment, Industrial wastes, Water treatment facilities, Biological oxygen demand, Suspended solids, Aerated lagoons, Chemical treatment, Alum, Coagulation.

With the help of chemicals and specialized flexible waste treatment equipment, about 33,000 Gpd of non-uniform wastewater is treated at the Gunnison Brothers tannery in Pennsylvania. The wastewaters typically contain lime, hair and other protein, grease and fatty acids, and numerous acids and dyes. A batch type system is used in the wastewater treatment facility. Jar tests are performed daily to determine how the influent will be treated. Use of alum as the primary coagulant in conjunction with other coagulant aids has enabled the tannery to meet regulatory requirements. The company reduced suspended solids from an average of 10,000 mg/liter to 80 mg/liter; oil and grease is reduced from 30 to 10 mg/liter. BOD in the influent is about 2,000 and is reduced to 200 mg/liter. COD is reduced from 15,000 to 1,000 mg/liter. Ammonia is reduced from 100 to less than 50 mg/liter. The primary effluent is pumped to a 450,000 gal aerated lagoon, where detention time is 6-10 days. From the aerobic lagoon the wastewater is pumped to a 55,000 gal secondary settling tank for final liquid/solids separation. Wastewater in the lagoon has picked up biological sludge which is treated in the secondary treatment tank. After flocculating, settling and clarifying the wastewater is disinfected and discharged. The clear effluent flows into Brandy Run, a tributary of Elk Creek which feeds Lake Erie. Dried sludge is hauled off to a sanitary landfill. (Baker-FRC)

REMOVAL OF PRIORITY POLLUTANTS,
Du Pont de Nemours (E. I.) and Co., Deepwater, NJ.
D. G. Hutton.
Industrial Wastes, Vol 26, No 2, p 22, 24, 26, March/April, 1980. 6 Tab.

Descriptors: *Industrial wastes, *Chemical wastes, *Wastewater treatment, Water treatment facilities, Wastewater, *Organic compounds, Heavy metals, Acid water, Sludge, Activated sludge.

Du Pont's Chambers Works in Deepwater, New Jersey, has an effective method of handling pollutants from an organic chemicals manufacturing site by neutralization and settling followed by a combined powdered carbon-biological process. The wastewater ranged from 23-50 million gallons per day. Lime slurry is added for neutralization; polyelectrolyte is added to aid in coagulating the fines prior to primary clarification. Primary sludge settles and thickens in clarifiers, is pumped to storage tanks and filtered to 45% solids concentration, and is disposed of in a lined landfill. Powdered activated carbon is added to the primary clarifier effluent as it is fed to the secondary/tertiary biological aeration tanks. The wastewater is strongly acidic, highly colored and of medium strength. Its BOD/DOC ratio suggests a high fraction of non-biodegradable compounds. The water is slightly brackish and has a relatively low suspended solids content. Primary treatment consisting of lime neutralization and settling was far more important for metals removal than the PACT process. There are at least 20 organic priority pollutants in the plant's wastewater. Thirteen of these are in the volatiles category. The secondary/tertiary PACT process does an effective job of removing organic pollutants, with 90% removal achieved for 13 of them and greater than 75% for 18 of the 20. (Baker-FRC)

MECHANISM OF CHARGED MEMBRANE ULTRAFILTRATION OF SALT SOLUTIONS,
State Univ. of New York at Buffalo. Dept. of Microbiology.
C. J. Van Oss.
Separation Science and Technology, Vol 15, No 2, p 159-161, 1980. 7 Ref.

Descriptors: *Acid mine water, *Filtration, Mine drainage, Acid streams, Acidic water, Membranes, Mine wastes, Industrial wastes, Membrane processes, *Membrane filters, *Wastewater treatment, *Ultrafiltration.

Optimal electrolyte removal by charged membrane ultrafiltration from acid mine water is discussed. A positively charged membrane would be the most effective, given the preponderance of bi- and trivalent cations, in which case the anions used would preferably be monovalent, and since low pH would be desirable to enhance the membrane potential, acidification with hydrochloric rather than sulfuric acid would be preferable. There does not appear to be any advantage in generating greater upstream turbulence than that corresponding to a Reynolds number of about 2500. As high a pressure differential as is compatible with membrane longevity and energy cost should be aimed for, so as to maximize the streaming potential across the pores of the membrane skin and thus the eletrolyte retention. Salt retention is likely to be increased by higher temperatures of operation due to the influences of temperature on viscosity, conductivity, and dielectric constant of the solution. If, for reasons of longevity, anionic membranes are preferred, sulfate will lead to a better salt retention than chloride ions, but then a high pH will be more advantageous to attain maximum membrane and streaming potentials. FUNGAL DECOLORIZATION OF KRAFT BLEACH PLANT EFFLUENTS,
North Carolina State Univ. at Raleigh. Dept. of Wood and Paper Science.
D. Eaton, H-M. Chang, and T. K. Kirk.
Tappi, Vol 63, No 10, p 103-106, October, 1980. 8 Tab, 10 Ref.

Descriptors: *Color removal, *Pulp and paper industry, *Fungi, Industrial wastewater, Wastewater treatment, Kraft mills, Effluents, Biological treatment.

Color was reduced by 60% in two to four days in kraft bleach plant effluents using the white rot fungus, Phanerochaete chrysosporium. Optimum conditions for decolorization were different from those favoring fungal growth. If the fungus was first allowed to grow at optimum pH, 4.3-4.8, decolorization then proceeded rapidly as low as pH 3. The best temperature for growth was 40 degrees C, but decolorization took place at temperatures as low as 28 degrees C. These results suggest that fungal decolorization is a secondary metabolic event attributable to lignin metabolism. The decolorization continued for 25 days, after which it was necessary to add glucose or cellulose, but not nitrogen. The decolorizing continued for at least 60 days before fresh cellulose was needed. Sodium chloride up to 6000 ppm did not significantly inhibit decolorization. (Cassar-FRC)

ANAEROBIC BIOLOGICAL TREATMENT OF FOOD INDUSTRY WASTEWATERS,
Water Pollution Research Lab., Stevenage (England).
F. E. Mosey.
Water Pollution Control, Vol 80, No 2, p 273-291, 1981. 9 Fig, 3 Tab, 25 Ref.

Descriptors: *Food processing industry, *Wastewater treatment, Industrial plants, Anaerobic digestion, Effluents, Food-processing wastes, Industrial wastes, Bacteria.

High-rate biological filtration through plastic media is a rugged, reliable treatment process capable of operating at high organic loadings of two to four kg BOD/cubic meter, which is well in excess of those sustainable in conventional activated-sludge plants or biological filters. The use of anaerobic digestion for the treatment of wastewaters incurred in food processing industries is becoming more and more appealing. Over the past 10 years there has been a worldwide reawakening of interest in this method of digestion, and the process is making great strides on several fronts in the food industry. Hydrogen-utilizing methane bacteria can now be isolated and grown on a large scale in pure cultures. The biochemical pathways of these bacteria are now being studied, with new information being gained into the microbial ecology of the anaerobic digestion process. The translation of these fundamental studies into kinetic data for the process engineer is spawning a new type of anaerobic biological treatment plan every five years. The anaerobic-digestion process is currently the main research topic in the field of wastewater treatment, and its potential for treating warm, moderately concentrated waste waters, especially those produced by the food industry, is both large and increasing rapidly. THE CONTROL OF BACTERIAL POLLUTION CAUSED BY SEA DISCHARGES OF SEWAGE,
Wessex Water Authority (England).
R. G. Toms, C. L. Saunders, and E. Hodges.
Water Pollution Control, Vol 80, No 2, p 204-220, 1981. 9 Fig, 1 Tab, 4 Ref.

Descriptors: *Pollution control, *Wastewater disposal, Outfall, Chlorination, Disinfection, Bacteria, Outfall sewers, Sewers, Seawater, Wastewater treatment, Coastal waters, Water pollution control, *United Kingdom, Wessex, Model studies.

An EEC directive has imposed bacterial levels on bathing water that are considerably more stringent than frequently is true in inland rivers, particularly

downstream from sewage treatment works. The EEC directive has been aimed primarily at protecting the environment and public health. Two methods used in the Wessex Water Authority area to control the bacterial level of bathing waters are described. The siting of a long sea outfall, now being studied at various positions off the Dorset and Somerset coasts, is one method. Use of chlorination to disinfect one important short sea outfall from the Avon coast is the second method. Model studies are being devised to gain more information on the long sea outfall. The studies will consider the effect of winds, including wind-generated shear, and also the effect of the sea bed in reflecting the sewage plume. Chlorination studies have shown this to be an inexpensive method of reducing bacterial populations of bathing water in this area. The total capital cost of equipment was less than 0.5% of the cost of construction of a long sea outfall. Chlorination should, however, be looked on as a short term solution only. (Baker-FRC)

APPLICATION OF IMMOBILIZED HYDROGENASE FOR THE DETRITIATION OF WATER,
Massachusetts Inst. of Tech., Cambridge. Lab. of Applied Biochemistry.
A. M. Klibanov, and J. Huber.
Biotechnology and Bioengineering, Vol 23, No 7, p 1537-1551, July, 1981. 8 Fig, 35 Ref.

Descriptors: *Catalysts, *Tritium, *Radioactive wastes, Nuclear powerplants, Waste treatment, Bacteria, Enzymes, Hydrogenase, Alcaligenes eutrophus, *Platinum, *Wastewater treatment, Isotope fractionation.

Removal of tritium from water contaminated during nuclear power production was accomplished by a catalyzed hydrogen isotope exchange process using immobilized hydrogenase in place of the commonly-used platinum catalysts. Whole bacterial cells of Alcaligenes eutrophus immobilized in calcium alginate or K-carrageenan gels were efficient catalysts for the reaction of hydrogen-tritium (H-T) exchange in both a batch tank reactor and a column. This enzymatic exchange (an equilibrium between HT + H20 and H2 + HT0) was not controlled by diffusion, as shown by the dependence of the reaction rate on the amount of immobilized cells in the system and the concentration of cells in the matrix. These immobilized cells were active over a wide pH range with a maximum at 6.0-8.0 and were quite resistant to hydrogenase inhibitors such as oxygen and carbon monoxide. The rate of the exchange reaction increased five fold upon increasing the temperature from 4 to 37 C. Ten grams of cells (wet weight) were equivalent in catalyst efficiency to 1 gram of Pt02. The bacterial hydrogenases are inexpensive, readily available, and very active in water. (Cassar-FRC)

VEGETATIVE FILTER TREATMENT OF LIVESTOCK FEEDLOT RUNOFF,
Nebraska Univ. Lincoln. Dept. of Agricultural Engineering.
E. C. Dickey, and D. H. Vanderholm.
Journal of Environmental Quality, Vol 10, No 3, p 279-284, July/September, 1981. 7 Fig, 5 Tab, 16 Ref.

Descriptors: *Feedlot runoff, *Land disposal, *Biofiltration, Runoff, Filtration, Nutrients, Biological oxygen demand, Water quality, Water pollution control, Animal wastes.

Four vegetative filters installed on feedlots in central and northern Illinois were evaluated over a 2 year period to determine the feasibility of using these systems for the management of feedlot runoff. Both channelized flow and overland flow systems were studied. Partial solids removal was achieved by settling, following which the runoff was applied directly to the experimental plots. Samples of influent, effluent, and surface flow at intermediate points were analyzed. There was no filter discharge from most runoff events. Runoff from larger events was partially discharged. Treatment with the vegetative filters resulted in reductions of nutrients, solids, and oxygen-demanding materials in the runoff of over 80 percent on a concentration basis and over 90 percent on a weight basis. Both the type of flow and the length of flow affected the degree of pollutant removal. Overland flow systems were more effective than channelized flow systems. Channelized flow systems required much greater flow lengths than overland systems for a similar degree of treatment. The discharge concentrations did not meet water quality standards for the receiving streams. The vegetative filters did not significantly reduce bacteria levels in the runoff. The study results indicate that discharge from adequate size vegetative filters ocurs only during large runoff events, when stream flows are also high, and that the overall impact of multiple vegetative filter systems appears to be negligible. LOW-COST WASTEWATER TREATMENT,
C. E. Morris.
Food Engineering, Vol. 53, No. 7, p 51-56, July, 1981. 3 Fig.

Descriptors: *Food-processing wastes, *Wastewater facilities, *Construction costs, Food processing industry, Industrial wastes, Costs, Oily water, Separation techniques, Runoff, Cooling water, Wastewater treatment, Vegetable oil refinery.

The nation's largest independent vegetable oil refinery located in Opelousas, Louisiana, designed and built wastewater treatment facilities to meet federal requirements in one year. Simplicity and redundancy were the keys to designing and building a system to handle both current and future flows. The engineering team hired by the company acted as its own design engineer and general contractor, but used some outside consultants. This approach helped keep costs at 2.2 million. The plant was designed to treat 121,000 gal/day and to handle increased effluent load in the future. Costs were also reduced by using simple oil/water separators in the form of gravity-separation decanters built of fiberglass reinforced plastic. Redundancy in the system permits components to be shut down for cleaning or repair without disrupting the system operation. All pumps were installed in pairs so system operation will not be jeopardized by pump failure. The system treats three wastewater streams: process wastewater, rainwater runoff, and cooling water. Chemical, mechanical, and biological processes are used. Oil residues collected by the stream are approved for soil enrichment. (Small-FRC)

PURIFICATION OF WASTEWATER BY ELECTROLYSIS,
Chile Univ., Santiago. Dept. of Fisica.
S. Contreras, M. Pieber, and J. Toha.
Biotechnology and Bioengineering, Vol 23, No 8, p 1881-1887, August, 1981. 9 Fig, 1 Tab.

Descriptors: *Electrolysis, *Bacteria, *Disinfection, Flocculation, *Wastewater treatment, Microbiological studies, Hydrogen ion concentration.

A simple and rapid wastewater treatment procedure is presented which is based on an electrolytic treatment. Wastewater samples containing an equivalent of 1 g of total solids per liter and about 10 to the 6th power microorganisms per liter were processed. Electrolysis was carried out at 30 V and 200 mA in a cell with two electrodes separated by an asbestos plate. Flocculation of the suspended material present in the wastewater was followed by optical density measurements. The number of microorganisms was evaluated before and after treatment. The percentage of microorganism survival decreased exponentially with increasing electrolysis time. The percentage of microorganisms decreased exponentially with increasing water volume. The effect of pH on microorganism viability was also investigated, and above and below neutral pH the percentage of microorganism survival decreased exponentially. Thus, the method can be used to produce clarified water free of microorganisms. (Small-FRC)

SEDIMENTATION OF ZEOLITE TYPE A IN WATER AND WASTE WATER,
Imperial Coll. of Science and Technology, London (England).
M. J. T. Carrondo, R. Perry, and J. N. Lester.
Canadian Journal of Civil Engineering, Vol. 8, No 2, p 206-217, June, 1981. 9 fig, 6 Tab, 35 Ref.

Descriptors: *Sedimentation, *Zeolites, *Wastewater treatment, Sedimentation rates, Activated sludge, Detergents, Suspended solids.

Zeolite type A is a synthetic aluminosilicate which has been considered as a possible substitute for phosphorus builders in detergents. A series of experiments was conducted to investigate the settling characteristics of zeolite type A in water and waste water. Settling column tests yielded results which compared well with predictions made by applying Stokes' law to the particle size distribution curves, despite the non-sphericity of the particles. Predictions of removals at different overflow rates made from the column tests were in substantial agreement with the results of the model sedimentation tank tests. Zeolite type A removal in water was low even at low flow rates. The presence of zeolite type A resulted in slight reductions of the percentage of suspended solids removed in static column tests using raw sewage. Zeolite type A was removed to a lesser extent than the other suspended solids, particularly during the initial stages of settling tests. Zeolite type A removal averaged 88 percent in activated sludge pilot plant tests. These results indicate that zeolite type A removals higher than 80 percent can be anticipated in wastewater treatment facilities using primary settling and secondary treatment by activated sludge; removals greater than 90 percent are regarded as probable. PILOT PLANT PERFORMANCES IN MUNICIPAL WASTEWATER TREATMENT BY ACTIVATED CARBON ADSORPTION,
Lagos Univ. (Nigeria). Dept. of Civil Engineering.
K. O. Iwugo, and R. J. Martin.
Effluent and Water Treatment Journal, Vol 20, No 7, p 327-329, 332-336, July, 1980. 6 Fig, 2 Tab, 30 Ref.

Descriptors: *Activated carbon, *Organic compounds, *Adsorption, *Pilot plants, Color removal, *Wastewater treatment, Organic carbon, Suspended solids.

A 0.5 cu meter per day sand-anthracite filtration-carbon adsorption pilot plant was operated under varying hydraulic loadings, organic loadings, and pH conditions to study removal of organics from municipal wastewater effluents. The carbon bed effluent organic carbon concentration varied almost directly with the concentration in the efluent after a steady state had been reached. This indicates that a certain fraction of organics in the

biologically treated sewage effluent cannot be adsorbed in this system no matter how the operating conditions are varied. The removal rates for various parameters (in mg per liter) in the granular carbon bed are summarized as follows: total organic carbon, 46.1%; soluble organic carbon, 49%; suspended solids, 56.8%; BOD5, 55.1%; BOD20, 24.5%+ and color, 90%. DAIRY LIQUID WASTE DISTRIBUTION IN AN OVERLAND FLOW VEGETATIVE-SOIL FILTER SYSTEM,
Southern Illinois Univ. at Carbondale. Dept. of Agricultural Industries.
J. J. Paterson, J. H. Jones, F. J. Olsen, and G. C. McCoy.
Transactions of the ASAE, Vol 23, No 4, p 973-977, 984, July/August, 1980. 3 Fig, 3 Tab, 6 Ref.

Descriptors: *Industrial wastewater, *Dairy industry, *Land disposal, Animal wastes, *Wastewater disposal, Wastewater irrigation, Overland flow, Water pollution control, Vegetation, Soil-water-plant relationships, *Feedlot wastes.

A vegetative-soil filter system provides a disposal method for livestock wastes which small operators can install themselves and which may be substituted for a zero-discharge system where the dairy herd comprises 100 cows or less. Distribution and management problems resulting from the use of 10 centimeter diameter polyvinyl chloride (PVC) pipe for a 'sheet flow' vegetative-soil filter system for liquid wastes from a 70 cow dairy operation are discussed. The liquid dairy wastes consisted of liquid waste from the feedlot resulting from runoff during rainfall and snowmelt plus liquid waste from the milking parlor and milkroom washwater. The width of effluent discharge was too narrow to make the best use of the utilization area when the pipe distribution line was shorter than 9 meters. Distribution lines longer than 30 meters were difficult to level for uniform flow. Under wet conditions, 1 gallon per square yard per day was found to be a safe loading rate for the filter area, except during rainfall and snowmelt events. During high rainfall events, pollution can be minimized by increasing the flow distance from the settling basin to the disposal area. The botanical composition of the filter area changed significantly over the 2-year period during which wastewater from livestock was applied daily to tall fescue sod. Maintaining a suitable grass cover was a major problem. The advantages of rotating between two or more utilization areas on a weekly basis with respect to maintenance of a grass cover are being investigated. Analysis of effluent samples from the disposal sites showed that the grass filter effectively removed pollutants from the liquid dairy wastes. (Carroll-FRC)

SEPARATION OF SELENIUM FROM SULFIDE LEACH LIQUORS,
Canmet, Ottawa (Ontario). Mineral Sciences Lab.
V. S. Sastri, and K. S. Subramanian.
Separation Science and Technology, Vol 15, No 1, p 75-79, 1980. 2 Tab, 7 Ref.

Descriptors: *Selenium, *Leaching, Metals, *Industrial wastes, Wastewaters, *Wastewater treatment, Coprecipitation, Cation exchange, Ion exchange.

The removal of selenium from leach liquors and metal-barren effluents before discharging into the natural waterways is essential due to the fact that selenium and its various compounds are extremely toxic and carcinogenic. A systematic study of the separation of selenium from leach solutions is presented. Selenium can be separated as the thiol complex by the procedure of Kovalskii. To effect removal as cuprous seleinde, buffer solution composed to citric acid and copper sulfate with a pH of 4.5 and aqueous ammonia was added to neutral Se(IV) solution. Aqueous hydroxylamine sulfate solution (1 ml of 10% solution) was added, and the mixture placed in a small funnel in the neck of a flask. After boiling and subsequently cooling, the contents were filtered through a microfilter stick. Separation as lead selenite is achieved by the procedure of Jachwerth based on coprecipitation of selenite as lead selenite with lead sulfate, which is subsequently dissolved in ammonium tartrate solution and the solution analyzed for selenium by a spectrophotometric method using 3,3'-diaminobenzidine as the organic complexing reagent. The separation of selenium by coprecipitation with arsenic is also possible. To achieve separation by cation exchange, an ion-exchange column 30 cm long and 2 cm in diameter is filled with cation exchange resin. The selenite solution is passed through the column; the effluent is collected and analyzed for selenium by a spectrophotometric method using 3,3'-diaminobenzidine as the complexing agent. Of these methods, the cation exchange chromatographic method gave the best separation. Coprecipitation with arsenic gave poor results. High recoveries were obtained in the case of separation as cuprous selenide. (Baker-FRC)

FLOC/FLOAT SYSTEM CLEANS DESALTER EFFLUENT,
Pielkenrood-Vinitex, Assendelft (Netherlands).
H. Kleen, and H. Marson.
Oil and Gas Journal, Vol 78, No 36, p 76-78, 80, September 8, 1980. 4 Fig, 1 Tab, 3 Ref.

Descriptors: *Industrial effluents, *Flocculation, *Wastewater treatment, Refinery wastes, Water treatment, Chemical coagulation, Dispersants, Emulsions, Industrial wastes, *Oil industry.

Difficult and expensive problems were caused by emulsions that formed in desalter effluent water from a Dutch refinery. The problematic emulsions formed, both water-in-oil and oil-in-water, had formerly passed through the system unseparated. They were removed with the oil and passed through a complete circuit. They built up in the cycle until on some occasions the separator system became blocked by viscous, jelly-like masses of emulsion. Solution was achieved by a design employing flocculation in a tilted plate flocculator and flotation. Alum was chosen as flocculant. Flotation was achieved by microbubbles generated from pressurized dissolved air. The treated water which flows into the main waste water treatment system is sufficiently purified to fall within the specification of 30 mg oil/kg which the refinery is expected to meet. The improvement of desalter effluent quality has reduced the frequency of plant shutdown due to exceeding the allowed population equivalent limit in the water discharge from four shutdowns to one shutdown per year. Descriptors: *Algae, *Biological wastewater treatment, *Water reclamation, Wastewater treatment, Feeds, Reviews, Economic aspects, Bacteria, Waste treatment, Spirulina, Chlorella, Scenedesmus, Irrigation water, Manure, Animal wastes, Chemical wastes, Effluents, Lagoons, Algae harvesting, Agriculture, Protein, Tropical regions, Impaired water use.

Mass production of microalgae is reviewed with special emphasis on the most promising technology, treatment of wastewater with algae-bacteria systems to yield a proteinaceous biomass suitable as a food. These processes vary from growing Spirulina on fermented cow dung in a ditch in India to the sophisticated Japanese Chlorella factories. High rate algae ponds, which represent great improvement over sewage or effluent treatment in deep unlined ponds at long retention times, feature intensive mixing and night-time aeration. Results are aerobic wastewater treatment, reclamation of treated water for use in irrigation, and the proteinaceous algae-bacteria biomass suitable for animal feed. Least energy consuming harvesting methods are sedimentation, filtration, and flotation. Among the highest yield values reported are a mean efficiency of photosynthetic active radiation conversion of 4.8% in Bulgaria. Addition of organic substrates boosts the yields. Nutritional and toxicological aspects of algae culture are discussed. The most promising fields for increasing microalgae production are in cases where algae are obtained as byproducts from urban sewage treatment, animal wastes, mineral fertilizer wastewaters, soda manufacture from carbonate brine, and ammonia or urea manufacture. KINETICS OF NITRATE AND AMMONIUM UPTAKE BY THE TROPICAL FRESHWATER MACROPHYTE PISTIA STRATIOTES L.,
Guam Univ., Agana. Marine Lab.
S. G. Nelson, B. D. Smith, and B. R. Best.
Aquaculture, Vol 24, No 1/2, p 11-19, May, 1981. 5 Fig, 1 Tab, 19 Ref.

Descriptors: *Nitrogen, *Kinetics, *Aquaculture, Nutrients, Macrophytes, Ammonium, Nitrates, Tropical regions, Wastewater treatment.

The kinetics of nitrogen uptake were examined for a common freshwater macrophyte Pistia stratiotes L. Nitrate-nitrogen and ammonium-nitrogen uptake were examined over a wide range of substrate concentrations gather information which would be useful in the design of aquaculture systems for ammonium and nitrate removal. Nitrate uptake rates were higher after 24 hr of exposure to the nitrate source than immediately after exposure. The rate of uptake of nitrate-nitrogen was greater in the light than in the dark. Nitrate uptake followed a pattern which could be adequately described by the Michaelis-Menten expression. Ammonium nitrogen uptake response to substrate concentration apeared to be linear. Rates of ammonium-nitrogen uptake was similar in the dark and in the light. For any given dissolved nitrogen concentration, the rate of ammonium-nitrogen uptake was greater than the rate of nitrate-nitrogen uptake. (Baker-FRC)

POTENTIAL FOR LAND DISPOSAL OF TWO NONBIODEGRADABLE WASTES,
Delaware Univ., Newark. Dept. of Agricultural Engineering.
W. F. Ritter, R. P. Eastburn, and M. P. Neisser.
Transactions of the ASAE, Vol 24, p 945-950, July/August, 1981. 8 Fig, 5 Tab, 14 Ref.

Descriptors: *Land disposal, *Industrial wastes, Nylon, Waste disposal, Wastewater disposal, Groundwater, Water pollution sources, Groundwater pollution, *Nonbiodegradable wastes.

A series of laboratory and greenhouse experiments was conducted to evaluate the potential for land disposal of some nonbiodegradable nylon processing wastes. Two wastewaters from experimental nylon manufacturing processes were subjected to soil column, lysimeter, adsorption, phytotoxicity and biodegradation studies. The major objectives were to determine whether the wastewaters were degradated by soil microorganisms and whether land disposal could be used for the wastewaters. Two wastes of differing chemical composition were used in the study. The chemical oxygen demand concentrations of the leachate for wastes A and B versus the amount of wastewater applied at different loading rates was determined. At a low application rate of 1.3 cm/week, no leachate samples were collected for five weeks due to evaporation. In general, the soil column profiles did not remove any more COD after about 36 to 48 cm of wastewater was applied, indicating that adsorption of the organic material to the soil particles was small. The pH of the leachate varied from 5.0 to 8.0 for wastes A and B. Samples of leachate were collected for 15 weeks from the lysimeters after the initial wastewater application. Neither waste A nor waste B adsorption could be described by the Langmuir equation or the Freundlich equation. Wastewater was applied to the pots in the greenhouse study for 18 weeks. One week after application began, the grass being treated with waste B became chlorotic. High application rates appeared to have an adverse effect on the vegetation. It was concluded that the potential for using land treatment for nonbiodegradable wastes is limited. These types of wastes could cause serious groundwater contamination. (Baker-FRC)

EXTRACTING HEAVY METALS AND TOXIC ORGANICS FROM SLUDGE,
A. A. Kalinske.
Water/Engineering and Management, Vol REF, No HB, p R148-R151, 1981.

Descriptors: *Sludge, *Toxicity, *Wastewater treatment, Sludge thickening, Sludge drying, *Sludge disposal, *Heavy metals, Organic compounds, *Sludge conditioning.

In order to make a sludge or residue non-hazardous, it may be necessary to reduce its heavy metal content. Municipal wastewater treatment plant sludge from primary and secondary treatments will contain various amounts of toxic organics such as chlorinated hydrocarbons and toxic heavy metals. Most of these are only slightly soluble in water and tend to adhere to the suspended solids in the wastewater. The biological organisms in the secondary plant, especially those in the sludge process, have a considerable capacity to remove heavy metals present in fine particulate form and in soluble form. Metal concentrations in the raw sewage coming to any treatment plant are relatively low. Chemical treatment, such as for phosphorus removal, will usually cause additional heavy metals to be removed from the sewage by precipitation due to increases in acidity and by coagulation of colloids. The ratio of soluble to insoluble concentration of the various heavy metals in liquid sludge can be changed by the addition of chemicals for conditioning, if the pH is changed. An elevated pH will cause precipitation, to some degree, of most of the heavy metals present in solution. There are also systems for heat-treating a liquid sludge so as to condition it in order to obtain excellent dewatering without using any chemicals. The sludge is raised to a temperature of 180-210 degrees C, under pressure conditions, and held for about 30 min. Heat drying of sludge is done at some wastewater treatment plants to prepare a saleable product for use as a soil conditioner with some fertilizing properties. (Baker-FRC)
W82-00947

CONTROL SYSTEMS FOR RETURN AND WASTE SLUDGE,
Metropolitan Sanitary District of Greater Chicago, IL.
R. L. McCarthy, and R. L. Sokol.
Water/Engineering and Management, Vol REF, No HB, p R152-154, 1981. 3 Fig, 1 Tab.

Descriptors: *Sludge, *Control systems, Equipment, Sludge excess, *Wastewater treatment, Activated sludge.

Devices, instruments, and piping arrangements which may aid in the application of processes governing the return and wasting of sludge are discussed. Sludge level sensors, air lifts, and a variety of control arrangements in use are described. While air lift with gravity return is still the primary method of returning sludge in the district of Greater Chicago, several new devices have improved the process, one of which is the sludge level sensor. There are two types of sensors; one, a sonic sensor, is based on the fact that an ultrasonic signal will attenuate to a large degree when passing through a liquid containing suspended solids as opposed to passing the signal through clear water. The second, the light sensor, uses a highly sensitive photocell and an infrared or ultraviolet light source in a probe suspended in the tank. The system is presently arranged so that the return sludge rate may be selected and the system kept in balance automatically by variation of the waste sludge rate with changing level of the sludge blanket. All sludge withdrawn from the tank is air lifted into a return sludge channel. The return sludge flow into the aeration tanks is controlled, based on varying sewage flow and a preset return sludge ratio. The amount of lift needed to return final tank sludge back to the aeration tanks is usually less than 3 feet. The back-up system for all controls is the sludge level indicator. The operator on duty makes charts which show four circles and which are penciled in whenever the sludge reaches a certain indicator pipe. If necessary this information when given to the shift operator can be used to make adjustments. (Baker-FRC)

Water/Engineering and Management, Vol 128, No 7, p 47-48, July, 1981. 6 Fig.

Descriptors: *Bromine chloride, *Disinfectants, *Secondary wastewater treatment, Wastewater treatment, Chlorination, Fish, Toxicity.

Bromine chloride was cost competive and offered advantages over other disinfectants in field trials at an activated sludge secondary wastewater treatment plant in Sykesville, Maryland. The 5 min control point residual required was 0.8 ppm equivalent total chlorine to produce a < 200 fecal coliforms per 100 ml effluent level and low or nondetectable residual in the final effluent. In a 96-hour fish survival test with fathead minnows, no fish were killed by 8 ppm BrCl in effluent, while 100% were killed in 8 ppm C12 in effluent. Bromine chloride has several advantages over chlorine. It is liquid at room temperature, 12 times more soluble in water, and more effective at lower temperatures. Bromamines formed in the process are less stable and therefore less harmful to aquatic life. Total treatment costs in cents per 1000 gal based on a 100 mgd plant are 1.6 for chlorobromination (5 ppm) and 1.9 for chlorination/dechlorination/postaeration. (Cassar-FRC)

SLUDGE BLANKET IN ACTIVATED FINAL CLARIFIERS,
Envirex, Inc., Milwaukee, WI.
W. H. Boyle.
Water/Engineering and Management, Vol REF, No HB, p R124, R129-R130, 1981. 3 Fig, 3 Tab, 5 Ref.

Descriptors: *Clarifiers, *Activated sludge, Sludge, *Wastewater treatment, Clarification, Chemical precipitation, Water treatment.

Activated sludge acts as a liquid and therefore seeks its own level on entering the final clarifier of a wastewater treatment plant. The heavier mixed liquor, on entering the final clarifier basin, drops to the floor or sludge blanket. It then travels along the floor until it hits an obstruction such as the peripheral wall for the center feed clarifier. Activated sludge does not settle as a discrete particle, but rather in a hindered zone of influence, and not therefore governed solely by Stokes' law of settling. Activated sludge has no choice but to seek its own liquid mass level in a clarifier if no mechanical or hydraulic limitations are imposed on it. The sludge will not likely be a homogeneous solid mixture in the sludge blanket, nor will the sludge blanket have a constant concentration of solids per unit area of the tank floor. Since sludge in each plant is different, the relative concentration will vary, but the random pattern of the contour lines of sludge will probably not differ significantly. A theoretical removal point will pass through as many as eight different solids contours for half the basin. It would be most difficult to design a sludge collector for rapid adjustment to each different concentration point. Even if well defined radial concentration points did exist, it would be impossible to say where the heavy versus the light sludge would be at any given time. To satisfy most mass loading theories and practical applications of final clarifiers, the designer and operator must take into account that sludge will settle at a level elevation and should be removed to sustain this level. While the solids concentration in the sludge blanket is not perfectly uniform, the removal device should be designed as though it were. (Baker-FRC)

AUTOMATION OF NORWICH SEWAGE-TREATMENT WORKS: EARLY COST CONSIDERATIONS,
Anglian Water Authority, Norwich (England). Norwich Sewage Div.
J. Hemsley, and A. Latten.
Water Pollution Control, Vol 80, No 3, p 341-355, 1981. 2 Fig, 10 Tab, 7 Ref.

Descriptors: *Automation, *Cost analysis, *Wastewater treatment, Water treatment facilities, Maintenance, Operating costs, Maintenance costs, *Norwich, England.

The effects of automated procedures on operating costs experienced at the Norwich sewage treatment works are described. An actual savings of 25,900 pounds Sterling/year thought to be attributable to automation was realized on operation. The desludging of primary sedimentation tanks was not cost effective on automatic control. However, if the same system were to be designed today, the eight ultrasonic sludge density indicators currently employed could be reduced to two, and this fact alone would mean that the costs would approximately balance the tangible benefits. The performance of the activated sludge plant during the automatic control period was clearly superior to that during the period of manual control. In efforts to gain cost figures regarding dissolved oxygen control, the DO control system of the 27.5 tcmd design DWF six-channel diffused-air, activated-sludge plant used up to four EIL Makereth DO sensors, positioned at various points around the aeration channels. To obtain data for a manual vs. automated operation, the DO control system was shut down for a time period and the DO controlled by manual adjustments to blower speed. Records of labor, power consumption, and plant performance were kept. In both manual and automated periods of operation the plant was operating in a non-nitrifying mode, and air supplied above that required to satisfy base respiration was substantially used in carbonaceous oxidation. Comparing the final costs indicated by the systems showed a present value saving on automatic control of 122,506 pounds, which is about equal to 1.5 operators or about 64 man-hr/week. (Baker-FRC)

GUIDELINE TABLES TO INDUSTRIAL WASTES PROBLEMS.
Water and Pollution Control, Vol 119, No 6, p 10-12, June, 1981. 1 Tab.

Descriptors: *Wastewater treatment, *Industrial wastes, *Industrial wastewater, Water quality standards.

An extensive table is presented which outlines treatments available for industry's major problem wastes. The table lists the industry, its waste problems, possible treatments, and guidelines and standards for maximum concentrations. Industries considered include basic iron and steel, agricultural chemicals, inorganic chemicals, organic chemicals, food processing, metal working and finishing, petroleum and petrochemicals, mining and metallurgy, pulp and paper, transportation industries, and tanning and rendering. Most of these wastes are in the form of contaminated water, although solid wastes are also mentioned in the table when appropriate. (Small-FRC)

THE CAPE FLATS SEWAGE TREATMENT WORKS,
J. G. Brand.
Civil Engineer in South Africa, Vol 23, No 4, p 124, April, 1981.

Descriptors: *Wastewater facilities, *Water reuse, *Activated sludge process, Wastewater renovation, Potable water, Secondary treatment, Oxidation, Sedimentation, *South Africa.

The Cape Flats Sewage Works, which treats primarily domestic sewage, handles an inflow of 150 Mliters/day. The older Athlone Works treats primarily industrial wastes, which are generally too saline to be reclaimed for potable use. At the Cape Flats plant, sewage is screened and grit is removed before passing into primary settling tanks and then into aeration reactors. After secondary settling, the effluent is discharged into oxidation ponds. The sludge is ultimately sold as fertilizer. The project was started in 1977, and the final value of contracts awarded was R22 million. The architectural design of the facility won a commendation by the Concrete Society of Southern Africa. Buildings such as the inlet works and blower house comprise concrete portal frames clad in color-coated curved asbestos sheeting. Selection and design of the basic process were carried out with a view to immediate compliance with the final effluent standards, and to the utlimate objective of water reuse. (Small-FRC)

FLUIDIZED BED FOR BIOLOGICAL WASTEWATER TREATMENT,
Patras Univ. (Greece). Lab. of Applied Thermodynamics.
T. C. Stathis.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE1, p 227-241, February, 1980. 1 Fig, 1 Tab, 15 Ref.

Descriptors: *Biological wastewater treatment, *Fluidized beds, Wastewater treatment, Biological treatment, Fluidized bed process, Microorganisms, *Nassau County, New York.

A fluidized bed system is described that is used in the treatment of municipal wastewater from Nassau County, New York, at its 60 mgd treatment plant at Bay Park, New York. Using a pilot plant of 72,000 gal/day, the 94 mg/liter of incoming primary soluble BOD effluent was being reduced to 11 mg/liter within a 16 minute total detention time. The recycle ratio for this case was equal to 2.2. Sand was used as the granular medium in the fluidized bed; this acts as a support surface upon which the biological population grows. Wastewater is first pumped through a pressurized oxygen mixing tank, where it is hydraulically mixed with pure oxygen gas and subsequently fed to the fluidized bed reactor. The fluidization of the media allows solids to pass through, thus overcoming the problems associated with packed bed systems, such as plugging and frequent backwashing. The fluidized bed system offers a much higher surface area per unit volume of reactor on which the microorganisms grow, and therefore it can operate with much higher concentrations of biological mass than other systems. As a result, the fluidized bed system requires considerably less space and lower construction costs than other systems, and it should be considered as a welcome addition to the variety of wastewater treatment systems available. MUTLICHAMBER SEPTIC TANKS,
Connecticut Univ., Storrs. School of Engineering.
R. Laak.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE3, p 539-546, June, 1980. 3 Fig, 29 Ref.

Descriptors: *Septic tanks, *Effluents, Design criteria, Wastewater treatment, Wastewater, Planning, Suspended solids, Biological oxygen demand, Multichamber septic tanks.

The concept of a multichambered septic tank is considered in contrast to the single chamber tank, which is conventionally used for small flows only. Multichamber tanks appear superior to single-chamber tanks in that up to 50% less suspended solids remain in the effluent. A change from a single chamber to a multi-chamber tank can mean a change in suspended solids removal from 75% to 80%. This represents a 20% suspended solids load improvement on the seepage bed. The surface area/depth ratio for each compartment, the loading intensity, and the outlet configuration show a significant effect on effluent quality. While overloaded tanks will undoubtedly fail, multichamber tanks often perform longer at a more satisfactory rate. To be effective, septic tanks should have a detention period longer than 24 hr, an outlet configuration with a gas baffle, maximized surface area/depth ratio for all chambers, and a multichamber tank with interconnections similar to the outlet design. CATION TRANSPORT IN PACKED BED REACTOR OF SOIL,
Florida University, Gainesville, Agricultural Engineering Department.
A. R. Overman, B. R. McMahon, R. L. Chu, and F. C. Wang.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE2, p 267-277, April, 1980. 16 Fig, 1 Tab, 12 Ref.

Descriptors: *Soil disposal fields, *Cation exchange, Model studies, Tertiary wastewater treatment, Wastewater treatment, Municipal wastewater, Kinetics, Waste disposal, Wastewater disposal, Land disposal, *Ion transport.

Cation exchange is an important process in the land treatment of municipal wastewater, since it influences the availability of several nutrients for crop uptake as well as the buffer capacity of the system to shock loading. A model of cation transport through a packed bed of soil is presented. Components of the model include convection, dispersion, and ion exchange. The method of finite differences as proposed by Gupta and Greenkorn is used to obtain a mathematical solution to the nonlinear system. The component for cation exchange is based on second-order kinetics in accord with the law of mass action. For the experiments conducted the packed bed reactor was packed with Lakeland fine sand to a bulk density of 1.66 g soil per cubic meter and a porosity of 0.376. After purging the soil air with carbon dioxide, the reactor was saturated with distilled/deionized water to assure total saturation so that pore velocities could be calculated. Several pore volumes of ammonium chloride were passed through to saturate exchange sites with ammonium ion. The pH was adjusted to 6.5. Samples were analyzed for ammonium ion with a spectrophotometer, for potassium by flame photometry, and by titration for chloride ion. Experiments were conducted by switching between ammonium chloride and potassium chloride of the same molar concentration and at pH 6.5. The findings indicate that the dynamics of cation exchange in packed soil depend upon water flow and ionic composition of the soil solution. Increases in ionic strength or flow velocity greatly increase the rate of cation exchange. The performance of land treatment systems depends on intricate coupling among hydraulic, chemical, and biological processes. (Baker-FRC)

BIOLOGICAL TREATMENT OF SYNTHETIC FUEL WASTEWATER,
Carnegie-Mellon Univ., Pittsburgh, PA. Dept. of Civil Engineering.
R. G. Luthy, D. J. Sekel, and J. T. Tallon.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE3, p 609-629, June, 1980. 5 Fig, 4 Tab, 20 Ref.

Descriptors: *Biological wastewater treatment, *Coal gasification, Wastewater treatment, Nitrification, Biological treatment, Ammonia, Nitrogen, Biological oxidation, Oxygen demand, Biological oxygen demand, Industrial effluents, Effluents, Gasification.

The possibility of using biological methods for the treatment of wastewater heavily laden with organic contaminants arising from a coal gasification pilot process plant was investigated. The wastewater used was obtained from the Grand Forks Energy Technology Center gasifier in Grand Forks, ND. The wastewater effluent was double decanted to remove most of the tar and oil prior to shipment. The wastewater contains on the order of 0.4 equivalents per liter total ammonia and 0.4 equivalents per liter of alkalinity. Most of the ammonia present is present as free ammonia. Wastewater was pretreated by dosing with lime to precipitate alkalinity as a calcium carbonate sludge and to raise pH when air stripping ammonia. Ammonia stripping was done to prepare influent to the biological cells. Stripping lowered ammonia concentration from an average level of 5,150 mg/liter to 330 to 580 mg/liter. Lime pretreatment and ammonia stripping removed 84% of raw wastewater alkalinity and 91% of wastewater ammonia, resulting in a significant decrease in wastewater conductivity. COD demand was reduced by 14%. Sulfide was reduced to 5 mg/liter. Biological reactors were seeded with activated sludge. Treatment of ammonia stripped wastewater at 25% strength showed very stable operating conditions. Effluent volatile suspended solids and phenolics were low, there was high removal efficiency for thiocyanate and chemical oxygen demand, and nearly complete nitrification of influent ammonia was achieved. Final studies showed wastewater could be processed at 40% strength and that nitrification was feasible with both stripped and unstripped wastewater. (Baker-FRC)

VACUUM FILTRATION OF METAL HYDROXIDE SLUDGES,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Civil Engineering.
W. R. Knocke, M. M. Ghosh, and J. T. Novak.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 106, No EE2, p 363-376, April, 1980. 9 Fig, 1 Tab, 14 Ref.

Descriptors: *Sludge, *Vacuum filtration, Sludge dewatering, Filtration, Metals, *Wastewater treatment, Industrial wastes, Separation techniques.

The characteristic response of metal hydroxide sludges to vacuum filtration was examined. Both individual and mixed-metal sludges were examined regarding sludge dewatering rates, handling properties, and filtrate quality obtained during vacuum dewatering. Sludge parameters such as mean particle size and size distribution, as well as operational

parameters such as precipitation pH, were evaluated to better define their effect on the dewatering of metal hydroxide sludges. It was concluded that most metal hydroxide sludges will yield acceptable dewatering rates when subjected to vacuum filtration. Sludges of high specific resistance can be conditioned through the addition of high molecular weight polyelectrolytes. The penetration of solids during vacuum dewatering must be dealt with for certain metal hydroxide sludges. Small additions of polyelectrolyte were helpful in minimizing the amount of solids in the vacuum filtrate. Sludge floc size had the greatest effect of those parameters tested on the rate at which metal hydroxide sludges dewater. Increases in the mean floc size of a sludge produced significant improvements in the rate of sludge dewatering, as evidenced by decreased sludge specific resistance values. Insolubilization pH and variations in metal content altered sludged specific resistance by affecting the size of flocs formed during the precipitation phase of treatment. Synthetic polyelectrolytes condition metal hydroxide sludges through increases in particle size. The mechanism of polymer action appears to be interparticle bridging. (Baker-FRC)
